ARE VITAMINS ALWAYS ENOUGH?

In malnutrition, convalescence, anorexia and old age, more than vitamins are often indicated. Besides vitamins there are maltose, dextrose and dextrans and other food elements present in Maltine with Vitamin Concentrates.

Some of the food elements in Maltine with Vitamin Concentrates—
approximate content per 30 cc (2 tablespoonfuls)

| | |
|------------------------|--------------------|
| VITAMIN A | 10,000 U S P units |
| VITAMIN D | 1,000 U S P units |
| THIAMINE HYDROCHLORIDE | 3 mg |
| RIBOFLAVIN | 4 mg |
| NICOTINAMIDE | 40 mg |
| + MALTOSE | 9.6 gm |
| + DEXTROSE | 4.2 gm |
| + DEXTRINS | 10.2 gm |
| + PHOSPHORUS | 279 mg |
| + CALCIUM | 303 mg |
| + CHOLINE* | 36 mg |
| + INOSITOL* | 44 mg |
| + FOLIC ACID* | 22 mcg |

*These constituents are members of the natural B Complex. Their need in human nutrition has not been established.

Two tablespoonfuls supply at least twice the minimum daily requirements of the above vitamins and supplementation of other easily digested food elements. The Maltine Company, New York 22.

MALTINE WITH VITAMIN CONCENTRATES

'm going to grow a hundred years old!"

*and possibly she may—
the amazing strides of
medical science have add-
years to life expectancy*

● It's a fact—a warm wonderful fact—that this five-year-old child, or your own child, has a life expectancy almost a whole decade longer than was her mother's, and a good 18 to 20 years longer than that of her grandmother. Not only the expectation of a longer life but of a life by far healthier. Thank medical science for that. Thank your doctor and thousands like him toiling ceaselessly that you may enjoy a better life.

According to a
recent independent
nationwide survey

SUGAR COATED!

It's a bitter pill for the patient when advised to wear
an orthopedic shoe . . .

But the "pill" can be "sugar-coated!"

For in *Pediformes* you have correct shoes that are as
pleasing to the taste as to the requirements of the
medical profession.

"Proper shoes" can be less objectionable if you will
prescribe *Pediformes*

 **Pediforme**

Synchronizing pituitary and ovary

When menopausal symptoms betoken an imbalance between the pituitary gland and ovary, PROGYNON B (alpha estradiol benzoate) injected intramuscularly will restore endocrine equilibrium safely, smoothly and more rapidly than any other estrogen. Therapeutic effects last from five to eight days depending on the dose administered and the severity of hormone deficiency.

PROGYNON-B

DOSAGE For average menopausal symptoms 0.33 mg. (2000 R U) once or twice weekly. Severe symptoms, as after surgical or x-ray castration, may require 1.0 mg. to 1.66 mg. (6000 to 10,000 R U) per injection.

PROGYNON B available in ampules of 1 cc. containing 0.08 mg. (500 R U) 0.16 mg. (1000 R U) 0.33 mg. (2000 R U) 1.0 mg. (6000 R U) and 1.66 mg. (10,000 R U).

"KI" the MODERN way

for conditions
requiring Potassium Iodide

SOLUTION FORMS of Potassium Iodide with variable dosages have proven to be largely unsatisfactory^{1,2} and there has been a long recognized need for a more accurate simple and convenient preparation

NEW ENKIDE (Brewer) fulfills this need—providing in a small, enteric-coated tablet, a full gram (15.43 grains) or a half gram (7.72 grains) of Potassium Iodide easy to prescribe and easier to tolerate with minimum gastric distress. Supplied 100 or 500 on prescription only—at a price acceptable to the average patient

and progressive wasting increases the gravity of the prognosis depletion of body proteins can be prevented. Parenamine—parenteral source of the indispensable and other amino acids—provides the elements of protein nutrition sustains the regenerative processes essential to recovery.

Parenamine

Amino Acids Stearns

PARENTERAL

For Protein Deficiency

PARENAMINE is a sterile 15 per cent solution of amino acids containing all known to be essential for humans, derived by acid hydrolysis from casein and fortified with pure di-tryptophane.

INDICATED in conditions of restricted intake, faulty absorption, increased need or excessive loss of proteins such

as in pre and postoperative management, extensive burns, delayed healing, gastro-intestinal disorders, et cetera.

ADMINISTRATION may be intravenous, intramuscular or subcutaneous.

SUPPLIED as 15 per cent sterile solution in 100 cc. rubber-capped bottles.

Reprints and complete clinical data will gladly be sent on request.

SPECIAL ANNOUNCEMENT

The new *Directory* is in process of preparation. All members are urged to return their cards at once. The deadline for insertions is July 1, 1946, after which date no changes in listings are effective.

Truly, this is America

the village church the white picket fence the
broad highways which lead to great cities
above all, the homes which breed good citizens

AMERICA'S strength is bred in her homes. In thousands of towns and cities, where modest bungalow stands proudly alongside a local show-place, where the well-kept lawn of one merges with its neighbor here, the roots of good citizenship are deeply planted

Here, too, strong bodies and good minds are built.

Because it is so American to want the finest, they will get it. In medicine, for instance, American hospitals, American practitioners are the envy of the world. In quiet towns or teeming

cities, the skilled hands of healing go about their work of keeping America well

To the science of Medicine the physician brings his own individual art of healing, for just as no two people are exactly alike, so no two cases of illness are identical

Thus, the physician must be free and unhampered, so that he may combine the *science* of Medicine, which is for humanity, with the *art* of healing, which is for the individual patient

At Ciba, in a quiet community of broad streets and pleasant lawns, we produce many of the fine pharmaceuticals used by the medical profession. In modern laboratories, Ciba medical scientists pursue their search for yet newer aids to physicians in their treatment of disease. This, too, is the American way

In treating Para-nasal Infection

Bacteriostatic Decongestion is the MEANS
Restoring Normal Function is the GOAL
 with **ARGYROL** *the Decongestant without Rebound Action*

In recent literature emphasis is being given to the after effects that frequently follow use of vasoconstrictors because of their rebound action

Such untoward results do not accompany the use of ARGYROL, the bacteriostatic decongestant that

AVOIDS THAT VICIOUS CIRCLE

When the physician uses ARGYROL he knows that he is contributing most to recovery through support of nature's own First Line of Defense

The cleansing, demulcent, bacteriostatic action of ARGYROL is attained by its three-fold action

Three-Fold Action of ARGYROL

- 1 ARGYROL is decongestive, without irritation to the membrane, and without ciliary injury
- 2 ARGYROL is powerfully bacteriostatic, yet is non-toxic to tissue
- 3 ARGYROL stimulates secretion and cleanses, thereby enhancing Nature's own first line of defense

Three-Fold Approach to Para-nasal Therapy

- 1 The nasal meatus by 20 per cent ARGYROL instillations through the nasolacrimal duct
- 2 The nasal passages with 10 per cent ARGYROL solution in drops
- 3 The nasal cavities with 10 per cent ARGYROL by nasal tamponage

ARGYROL *the Physiologic*
Anti-infective with broad, sustained action

Made only by the **A C BARNES COMPANY, NEW BRUNSWICK, N J**

Three drops of PRIVINE... and welcome relief!

Hay fever sufferers are finding prolonged symptomatic relief with minimal dosage—only three drops—of Privine, Ciba's potent vasoconstrictor.

Privine Hydrochloride acts quickly on the nasal mucosa without retarding ciliary activity. Its solution is buffered to a pH of 6.2, closely simulating normal nasal secretions.

Physicians will find that by advising their patients to use no more than the recommended three drops in each nostril, no oftener than three times daily, gratifying and prolonged relief will be experienced.

PRIVINE is available in two solutions: 1 per cent and 0.05 per cent, packaged in 1 ounce bottle with dropper designed to dispense but three drops—the recommended dose. Also available in bottles of 16 fluid ounces.

PRIVINE NASAL JELLY—Tubes of $\frac{1}{2}$ oz., containing 0.05% Privine Hydrochloride.

*Privine—Trade Mark Registered in U. S. Pat. Off.
Brand of Naphazoline Hydrochloride*

YOU CAN'T

overrate the value of CONTROL

It's spectacular, but brief—the kind of control that reigns beneath the big top each Spring

Less heralded is the day-in day-out control that rules each operation in the manufacture of pharmaceuticals in white-walled U D laboratories and production rooms For this is quality control It consists of a long-established, efficient system of tests which have won for these products an exceptional record for consistent quality.

Much credit for these fine results is due the body of doctors, chemists and pharmacists who set and maintain the high standards This group is U.D.'s famous Formula Control Committee which insists upon topping all previous precautions with a personal check of every finished formula

Interest, effort, care and experience combine to insure that your orders are filled with materials of unexcelled purity when you specify U.D. preparations The same qualities mark the service of your neighborhood Rexall Drug Store Additional features that patients appreciate are this store's convenience and economy.

ZYMONOL has long been recognized by obstetricians and pediatricians as an ideal bowel management therapy

Zymenol, a brewers' yeast emulsion,** aids restoration of physiological bowel content through zymolysis and helps to normalize intestinal motility with its complete, natural vitamin B complex content.

Soft, comfortable, regular evacuation is assured without catharsis or colloidal bulkage. Because Zymenol is agreeably palatable, sugar free, and the only emulsion effective in *teaspoon* doses, patient control is seldom a problem.

For patient-acceptable bowel management in a age group—specify Zymenol.
OTIS E. GLIDDEN & CO, Inc, Evanston, I

The Common Denominator of Reducing Diets

Whether weight reduction is to be brought about gradually, at the rate of a pound or two per week, or drastically at the rate of a pound per day, all reducing diets must recognize one cardinal requirement: the need for protein of the right quality in the right amount

Unless biologically adequate protein is supplied in the quantity normally required, the living tissue itself would suffer, tissue repair could not be carried on, hemoglobin regeneration would be impaired, antibody formation would be curtailed, resistance to infectious disease would be lessened, and production of enzymes and hormones would fall below the required level.

Lean meat may well be called the common denominator of reducing diets. Its protein content is notably high, and the protein it supplies is of high biologic quality, adequate for every protein need

healing sleep is one of the most effective therapeutic agents. But when clinical conditions alter sleep habits, adequate rest may be most difficult to secure.

When sleep patterns of your patients are altered, 'DELVINAL' sodium vinbarbital will provide a night of restful sleep in the majority of instances with relative freedom from unpleasant side-effects of excitation or 'hangover'. 'DELVINAL' sodium vinbarbital is a mild sedative that has a relatively short induction period and a moderate duration of action.

Council accepted, it may be prescribed for the relief of insomnia, for general sedation, preanesthetic hypnosis, psychiatric sedation, obstetric amnesia, and for numerous purposes in the field of pediatrics. Supplied in 32 mg ($\frac{3}{4}$ gr), 10 Gm. ($1\frac{1}{2}$ gr) and 20-Gm. (3-gr) capsules. Sharp & Dohme, Philadelphia 1, Pa.

Penicillin Schenley

Penicillin is the best agent available for the treatment of subacute bacterial endocarditis. Daily administration of 200,000 to 300,000 units or, in infections with resistant organisms, much more, in divided doses (every 3 hours) is required. Intramuscular injections are usually the route of choice, however, in certain instances, it may appear desirable to employ continuous drip. Therapy should be continued for a minimum of 3 weeks and must be continued until the blood cultures are consistently negative. Penicillin alone is as effective as penicillin and heparin combined.

Final determination of cure depends upon long term observation, but if the patient remains asymptomatic and bacteriologically free for a period of 4 weeks after cessation of penicillin therapy, the prognosis for complete cure is excellent. However, it must be remembered that valvular damage and renal lesions are not favorably influenced

For National Rehabilitation

Yes, it's a fact

In addition to its refreshing quality and its flavor, ice cream contains many important health giving food elements. It contains the following nutrients:

Vitamins Ice Cream is a good source of Vitamin A and Riboflavin (Vitamin G) and contains other vitamins found in milk.

Minerals Calcium, necessary for strong bones and teeth, is supplied abundantly by Ice Cream.

Proteins Ice Cream provides high quality proteins—those found in milk.

All of these nutrients promote health and well being.

And remember, the particular combination of nutrients found in Ice Cream is unusual. This is one reason why Ice Cream is accorded such an important role in our national rehabilitation program.

Ice Cream—Composition-Manufacture Food Value—an interesting, factual leaflet will be sent free on request. Write: National Dairy Council, Dept. P746, 437 Fifth Avenue, New York 17, New York.

MANDELAMINE

Reg. U. S. Pat. Off.
(Methenamine Mandelate)

IS AN ESPECIALLY EFFECTIVE URINARY ANTISEPTIC

Safety, ease of administration and characteristically prompt action combine to make Mandelamine an especially efficient agent in the treatment of urinary infections in children and in elderly patients.

Freedom from drug toxicity is an important consideration to the busy physician who is unable to maintain patients under close medical supervision. Mandelamine may be confidently prescribed in therapeutic dosage virtually without consideration of toxic effects.

Uncomplicated oral administration of Mandelamine requires no supplementary acidification, restriction of fluid intake, dietary control, or other special measures. Only in those infections due to urea-splitting organisms, may accessory acidification be necessary.

Early control of common urinary infections is the characteristic response to Mandelamine therapy. Disturbing urinary symptoms are usually alleviated rapidly and, in the absence of obstruction, the urine is promptly cleared of organisms in a high percentage of cases.

Mandelamine is supplied in enteric coated tablets of 0.35 Gm. (13½ grains) each, in packages of 170 tablets warranted, and in bottles of 500 and 1000.

FOR THREATENED AND HABITUAL ABORTION

In the treatment of habitual abortion, "vitamin E should be used because it appears to offer great hope in salvaging pregnancies that would otherwise habitually abort." * Ephynal Acetate—the Roche vitamin E preparation (α tocopherol acetate)—is particularly suitable for the treatment of habitual and threatened abortion because it is stable, of unvarying potency and purity, and well tolerated even in large doses and over long periods of time. Its freedom from side reactions is of signal value in all disorders amenable to vitamin E therapy. Available in tablets of 3, 10, and 25 mg.

to combat
the depression of

chronic organic disease Many patients with chronic organic disease—arthritis or asthma, for example—sink into a persistent depression characterized by discouragement, or even despair. Unless effectively combated, this depression may handicap management of the basic disorder and intensify its symptoms.

By restoring optimism and interest in useful living, Benzedrine Sulfate frequently helps to overcome prolonged depression accompanying chronic illness. Obviously, in such cases careful observation of the patient is desirable and the physician will distinguish between the casual case of low spirits and a true mental depression.

BORDEN IS PROUD TO PRESENT

Gerilac

A NEW DIETARY SUPPLEMENT FOR THE AGED

Gerilac has a milk-nature most perfect food—modified to provide a high protein and low fat content with the addition of other dietary factors considered essential in geriatric nutrition so that

Gerilac supplies in one reliquified pint at least one-third of the protein, a full allowance of each of the vitamins and minerals, and about one-tenth of the calories recommended for daily intake by the Food and Nutrition Board National Research Council

Gerilac offers these nutritional values in a palatable easily consumed and readily digestible form (suitable for use as a fever age or in Special Diets). It also lends itself ideally for the nutrition of convalescents and of pre- and postoperative cases.

The So-Called Physiological Anemia of Infants—

MOST infants experience a mild hypochromic anemia, due to iron deficiency in the dietary beginning at about the fourth month of life. This well known fact has for long been so lightly regarded that it is often referred to as the "physiological anemia" of infancy. That this is a misnomer is indicated by the work of Mackay* who following thorough and controlled studies, showed that (1) the anemia was preventable by iron medication (2) the anemia, though slight, lowered markedly the resistance of the child to infectious disease, and (3) growth was retarded by iron deficiency. Mackay's investigation showed that in babies given iron the incidence of infection was lower and its duration considerably shorter and that babies given iron averaged one pound heavier than those in the control group.

The conclusion was:

NO ANEMIA, EVEN OF SLIGHT DEGREE, IS INSIGNIFICANT because it is too important a factor in predisposing to infection.

It has been shown that homogenized iron-containing foods yield considerably more utilisable iron than similar foods which have been strained only. The texture of homogenized baby foods is so fine that they may be fed—mixed in the milk formula—through a nipple opening of ordinary size. Supplemental feeding of homogenized baby foods may be started as early as the fifth week of life, before the prenatal stores of iron are exhausted and before the usual anemia of infancy has set in. Only Libby's Baby Foods are homogenized as well as strained.

VOMITING OF PREGNANCY

Of the appetite stimulating B vitamins, the specific factors provided by Pyrrithiad most rapidly relieve the hyperemesis of pregnancy. This dangerous gastrointestinal disturbance which restricts absorption at a time of increased vitamin requirement, in many cases is promptly alleviated by injections of Pyrrithiad. Unless so relieved, nausea and vomiting of pregnancy may lead to polyneuritis, a symptom of profound thiamine deficiency. Pyridoxine hydrochloride and thiamine hydrochloride, as contained in Pyrrithiad act promptly and apparently with specificity in this condition. Pyrrithiad is supplied as a solution for intravenous or intramuscular injection and as tablets for oral use.

VOLUME 46

JULY 1 1946

NUMBER 13

Editorial

The Annual Meeting

The State Society held its 1946 annual meeting, the first general sessions since the close of the Great War, at the Hotel Pennsylvania in New York City from April 29 to May 3, 1946. The registered attendance of doctors, nurses, and students was 4,561. As of May 1, 1946, the total membership of the Medical Society of the State of New York was 19,940. Apparently, about one quarter of the members seems to have attended.

This is heartening both for the chairman of the sections who work long and hard to prepare their respective programs, for the exhibitors, who by their rental of exhibit space make the financing possible, and, likewise, for the Convention Committee of the State Society. The scientific exhibits this year were of more than usual interest and diversity. The availability of good photographic materials is to be noted, now that the war is over, and it is to be hoped that color photography will be developed more widely and used more freely than in the past.

The extended session of the House of Dele-

gates permitted more time for the work of the reference committees in the consideration of the annual reports of officers and of resolutions introduced by members. The account of these proceedings will be published in this issue and subsequent issues of the JOURNAL and deserves careful reading by the members of the society. The constituent county societies were each represented by full delegations and a thorough and complete discussion of all the business on hand prevailed. The Speaker of the House, Dr. Louis H. Bauer, conducted the meetings with his usual skill and competency and this was his final appearance in this capacity, for now he is the President-Elect.

An unusual feature of the meeting was the award of a prize, a well-behaved puppy, and several additional book prizes, for essays by school children on the use of animals for scientific experimental work. This marks the first time awards have been given outside the membership of the society itself, the presentations being made during the course of the final session and witnessed by the par-

ents of the winners and representatives of the New York City Public Schools

Among the important business matters transacted by the delegates were the final steps taken to establish a corporation by the society, authorized to enter into contractual agreement with the Veterans Administration to implement, for the entire State, local medical service for veterans with service-connected disabilities. It is hoped that a fair uniform fee schedule can shortly be instituted for the State as a whole and that

claims for services rendered in this program can be expedited as rapidly and satisfactorily as possible. The proposed arrangement should prove of mutual advantage to all concerned.

In this issue of the JOURNAL are contained the addresses made by guest speakers at the Annual Banquet, which merit the careful attention of our readers. The scientific papers presented at the Section Meetings will appear in subsequent issues, as well as the detailed proceedings.

Dr. Simon Flexner

Another great figure in American medicine passed away on May 2 at the advanced age of eighty-three. A renowned investigator in the field of infectious diseases in his own right, Dr. Flexner was the organizer and first director of the Rockefeller Institute for Medical Research, from which he retired in 1935 with the rank of director emeritus.

There were other distinctions. Among his achievements were the production of a curative serum for cerebrospinal meningitis, in cooperation with the late William H. Park and others, as well as his researches on poliomyelitis and the filterable viruses. In the first World War he developed our knowledge of the acute dysenteries while serving in the Philippines and was finally commissioned a lieutenant colonel.

Dr. Flexner's university connections were numerous and prominent and he was awarded many honorary degrees. He made many outstanding contributions to medical

literature. For many years he was a member of the State Society until his retirement. One of his signal contributions to the profession was his unfailing support of the efforts to curb the activities of the antivivisectionists. Year after year with a group of others interested in the subject, he appeared at the legislative hearings where his eminence as an investigator constituted a convincing argument in itself. One of the last acts of his long life was to lend his aid in the campaign against the recent antianimal experimentation bills, by his participation in the organizing committee of the Friends of Medical Research, which made a successful fight against these restrictive measures.

Simon Flexner had a long, eventful and successful career, as an investigator, a teacher, and an administrator. His noteworthy achievements in medicine mark him as an outstanding member of the profession, worthy of the many encomiums with which he has been honored.

Medical Publicity

Does good medicine get *good* publicity? Does it get *enough* good publicity? The answer to the first question is *no*. The answer to the second question is *no*. There is no doubt that good publicity men are to be had. There is also no doubt that here and there organized medicine has availed itself of their services, but as yet merely a small beginning has been made.

In the main, publicity is the art of bringing to the public consciousness items of

news relating to advancements in the science or the art of medicine, or of some event in which the practice of medicine is concerned.

Doctors more often than not have very little conception of the art of creating publicity. They have shunned it for themselves and have carried a distaste for it into their relationship with organized medicine. This has been a natural carryover and is quite understandable.

News paper editors and editors of periodicals which are popularly circulated are engaged in the job of publishing items concerning current events which, in their opinion, will interest and inform the public so that the public in turn will read their papers. They do not make the news, but they decide what is news and the emphasis and "slant" with which it is to be presented, making the effort with the better journals to be as objective as their opinions will allow them to be. Even so, the very function of selection and emphasis makes their judgments necessarily discriminating, depending on the conception each editor may have of his reader's threshold of acceptance.

Under the circumstances, it will be seen that for organized medicine to obtain publicity it must first select an idea or situation which can be presented to editors by a publicity man who knows how to do it interestingly, and finally, the editors will have to be convinced from the news release that the material is news which the readers of their periodicals or journals will wish to read. Because doctors are interested in an aspect of medicine, it does not follow that all of the public or even any considerable portion of the public is interested in the same aspect. The reader's chief interest is based on what the material may mean to him, now or in the future. The art of the publicity man's contribution is to find the least common denominator between the medical content and the reader's capacity to understand. The factual material must be oversimplified. The special skill required is to perform this feat without outraging the verities of the factual content, thus remaining on good terms with the medical man, while presenting to the public a partial, but not distorted, interpretation that the editor and reader will accept as having present or prospective effects on themselves, their families, or their friends.

A correspondent writes us to the effect that "Conscientious members of the medical profession today are pained because good medicine does not get good publicity. They read what the proponents of the Wagner-Murray-Dingell Bill have to say about the benefits that the people are about to receive, but they find little mention of what the medical profession has already done for them.

"There is now open at Number 30, Rockefeller Plaza an Exhibit of Naval Research and Inventions. Those who visit it are given a fifteen-page booklet. In it are shown diagrams of Atoms, demonstrations of Radar, Jet Propulsion and Guided Missiles. One-third of one page is devoted to the Exhibit of the Bureau of Medicine. The proportion is forty-four parts of destruction to the one of conservation. The forty-four parts are completely mysterious to the average observer. The one part is comprehensible to almost anyone. Yet forty-four to one is about the average ratio of news coverage accorded to the good deeds of medicine."

To answer our correspondent, we can only say that good medicine like good people, at least in this country, seldom is front-page news. Bad medicine, on the other hand, like crime, is newsworthy because it is exceptional and the more exceptional it is the more likely to make the front page.

Our correspondent continues, "The development of penicillin, the use of blood and blood substitutes in the treatment of shock, the reduction of the death rate of the wounded in World War II to 45 per cent from 820 per cent in World War I, three cases of tetanus among the immunized personnel in the Army, one case of tetanus among the battle casualties, these are astounding developments." They are. They are the result of superior research, superior applications of medical techniques. Many of these items have made the front page during the war, even under restrictions of censorship. But, having made the news in the original instance, they have no continuing newsworthiness except when new facts of usefulness are found and announced. What the doctor forgets, but the publicity man remembers every moment is that the word "news" is the plural of "new." The next thing forgotten by the one and remembered by the other is that news is based on *happenings* of today, not last week or last month. There must be an *event* to which the probative material in the release is tied. Early in the Committee hearings on the Wagner-Murray-Dingell Bill, the case on behalf of the bill was presented. Unless some member of the Committee, or the witnesses out of their own mouths made statements derog-

atory of the bill, and could be *quoted as so doing*, there was nothing for the news columns to the advantage of organized medicine in the events which occurred. When the other side—our side—is presented, the case should be different, provided there is somebody on hand to get the material to the newspapers in releases easy to read and ready to print.

Another thing which the publicity man bears constantly in mind is that statements for or against proposed legislation may be repeated in substance time after time, if uttered by some person, especially one whose title commands attention, at different public meetings, or on different occasions. The meeting is the basic *event* recounted in the press, the statements are a part of the event. Every publicity man knows this, and part of his job is to arrange occasions for public statements to be made, and it is his function to see that medical spokesmen make them with clearness, strength, brevity, and discretion. At times this may call for the combined capacities of a Chesterfield and a Machiavelli, for it is not always easy to get a doctor to say what he means, within the compass of what a newspaper will quote, and to omit what may harm his cause more than it helps. In a word, the doctor is an expert on the content, the publicity man is an expert in expressing the content effectively with the public. If, additionally to that, he is able to bring his clients to the point where they think always in terms of what their words will mean to the public (not merely to their own colleagues), and grant

the right of the public to have opinions, wrong or right as they may be, then the publicity man has grown into the exercise of a public relations function.

We think that our correspondent and many other physicians who are pained or discouraged in the matter of medical publicity might revise their views if they would take the time to study the mechanism of publicity and consider whether doctors are competent to handle it. We believe they are not, and we further believe that the more medicine employs competent public relations counsel, the better will be the impression made upon the public. True, they cost money. In the complicated civilization of today an idea is not self-propelled from the point of origin to its destination. If the idea is to be disseminated to large numbers of people, it will not run like wild fire among them without cost, as did the news of the Lincoln-Douglas debates, or even the McKinley-Bryan campaign speeches. The radio, the newspapers, the magazines, the movies, and the automobile subject the citizen to a continuous bombardment of impressions.

The idea that we wish every citizen to know must force its way among these distractions. The bill for the freight must be paid, made up of items for expert personnel, postage, mimeographing, printing. Skill and money are required if we are to be heard above the welter of confusing voices, shouting on every hand various ideas that are to somebody's advantage to impress upon the public consciousness.

Current Editorial Comment

Relationship of Industrial Physician
 "What," asks *Medical Economics*,¹ "of the relationship of the industrial physician and the employee? Industry should recognize that while the physician usually works for management and is paid by management his professional responsibility is primarily to the employee. His relationship with the employee should be the same confidential one which exists between the private practitioner and his patient."

It continues

When a plant health service is instituted, employees are frequently suspicious. They fear that management is trying to put something over, that it may be planning to use the service for its own ends, perhaps get rid of trouble-makers or men whose condition may increase

their compensation risks. Because of this suspicion, some employee groups have been slow to support industrial health service, and sometimes, though I think not often, with reason.

It is only as the integrity of the physician's position is completely demonstrated that suspicion can be removed. The plant physician must not permit his services to be used in the interest of management against employees, or in the interest of the employee against management.

The industrial physician usually does not practice curative medicine in the plant, except for minor ailments and in cases of emergency. After emergency treatment, the employee is referred to his family physician for treatment. This procedure must be clearly understood in the beginning. The physician must not overstep the line.

MORAL AND PSYCHOLOGIC ASPECTS OF THE CONTROL OF VENEREAL DISEASE

L. E. LUBERS, M.D., New York City

(*Psychiatrist to the Community Service Society*)

A PSYCHIATRIST cannot hope to give to a group of workers in the field of social hygiene any new knowledge. At best he can only try to contribute some new perspective and arouse some new lines of thought.

Those of us who work with the problems of people, either individually or as a group, often become discouraged. Progress seems slow in comparison with the effort made, and even in the vigorous reports from the field of social hygiene, a faint note of despair creeps in. Actually, one of the best ways to find courage is to look backward, not to yesterday but some 200 years to the middle of the eighteenth century. Anyone who reads the literature of that day must acknowledge that conditions have changed for the better. The gross self-indulgence, the gross disregard for human suffering, the self-complacency of the privileged few, the harsh repression of the unprivileged majority were then accepted as a normal way of life.

It was a long road from there to the present social conscience and our vast network of welfare work. The dramatic, though often sentimental, social-consciousness of the Victorian novelist, the doctrine of evolution and steady change that inspired the great scientists, the growing practicality of the economists and philosophers, all made the world aware that conditions were worse than they need be. In one field after another people were inspired to try to correct the evils and their efforts have been strikingly effective.

The possibility of eradicating venereal disease could hardly have been conceived of two hundred years ago. Much groundwork had first to be laid and, even now, the social hygienist struggles against tremendous obstacles. Perhaps the greatest of these is human nature itself. In a problem so intimately linked with the social and moral habits of a people, it is perhaps inevitable that progress should be slow. Not only the source of the infection but the actual occurrence of an infection is hidden away by the guilt of the patient. Other diseases may inspire horror and people may fear to acknowledge them but no others carry the same implication of delinquency and fear of punishment. The guilty patient only too often fears less the suf-

fering from the disease than the shame of confession. Each generation is born with the same deep instinctive needs, the same selfish egotism, the same greed to satisfy self before society. Faced with guilt, the average man thinks of protecting himself rather than the community. And to the average man, venereal disease is an unpleasant reality about which he has done his utmost by escaping from getting it himself. The external world has changed, one may truthfully say, for the better, we are perhaps learning how to prepare the young more adequately for the world as it is, but the essential nature of man remains.

One of the basic factors that we have to reckon with is the extent to which, in the vast complexity and growing efficiency of our civilization, we have developed the pattern of specialization. More and more we, as individuals, devote our energies to a narrow field and depend on others to supply the needs which once were the concern of every man. Even the farmer who has remained closest to our earlier self-sufficiency has forgotten many of his earlier skills. What city dweller could competently feed, clothe, or shelter himself, let alone protect himself against the inroads of disease? Our physical comforts, our security against human or animal enemies, our very lives depend upon the skills of professional specialists. We have gained much from this concentration of effort but we have also learned to lean on others, to pay with money for our ignorance and sloth, and to put so much responsibility upon the specialist to protect us that we as individuals are doing less than our share. We scatter paper or worse in the street, trusting to the sanitation department to clean it up. We pay social workers to care for the poor rather than caring directly ourselves for them. We try to get our sons back home before the war job is finished, trusting that the Government will manage somehow if we merely pay our taxes. And we leave it to the health authorities to eliminate disease, not wanting to be bothered with contributing anything more than money to the work. Although we have gained a social conscience, and recognize the need to deal with the ills of society, we have grown slack about giving toward their correction more of ourselves than our money, or a little of our time toward raising it. Having done that, we retreat into our own self-indulgence, leaving the real work to the paid

specialist We walk through life expecting protection from others and abandoning the effort to protect ourselves And in so unpleasant a field as that of venereal disease, it is even more convenient to leave the responsibility to others

It is hard to see how or why anyone could actually oppose a campaign to eliminate venereal disease from society The pain and disgust arising from a gonorrheal or chancroid infection, the discomfort and anxiety created by the later stages of syphilis must arouse a desire to avoid them in even the least intelligent person Information about these diseases has certainly been widely spread so that few people today are completely ignorant One rarely hears, now, the once popular statement among boys that they could best prove their manhood by acquiring gonorrhea

There are a few people whose sense of guilt about sex creates in them so strong a need for self-punishment that they may unconsciously seek infection On the whole, however, such people are few If venereal disease persists, it is not because of widespread neurotic compulsion nor because of ignorance

The treatment of the venereal diseases has had the attention of scientists who have found means of rendering the victims noncontagious within a short time, often with complete cure One of the difficult features of eliminating tuberculosis is that the disease once acquired is merely arrested and may again become an active source of contagion at any time This is not true of venereal disease, since it can be completely cured and so treatment actually eliminates the patient as the source of the disease And yet we know that some completely cured persons do acquire a new infection, proving that even personal experience has not deterred them It is conceivable that the effectiveness of treatment may have robbed the diseases somewhat of their terror, and so people are less fearful of getting them Even so, it is obvious that a large number of those infected do not seek treatment voluntarily It is no doubt true that public clinics are still far from ideal in the attention they give to the emotional reactions of their patients Not only the fear of unsympathetic handling but the association with undesirable characters and the chance of publicity may keep some from going for treatment There may, in fact, be a need for more and better facilities for therapy Still, during the war when more people than ever had money to pay to a private practitioner, the known venereal rate rose, which implied that many were going untreated It is really scarcely probable that either improvement in treatment or lack of suitable facilities has contributed appreciably to the spread of the diseases

It has been recognized that professional prostitution is a fertile source of infection The authorities and the protective agencies have waged a vigorous campaign against it The life of a prostitute is certainly not a pleasant one and economic conditions here and now rarely drive a girl into this life in order to live, as has been true in the past We have come to recognize that the prostitute is often driven by neurotic compulsion into this life Denied this form of expressing her neurosis, she may develop other symptoms It may be that the failure to check prostitution by repressive measures is due in part to failure to recognize that we are dealing with mental illness rather than with crime Still, the actual number of sufferers from this neurotic compulsion hardly accounts for the persistence of the practice Prostitutes would not exist if they were not used by men They may stimulate the interest of men but the desire must first be there And even without prostitution, promiscuous sex activity goes on

To all of these factors, the social hygienists have given much attention—to the spread of information, to the repression of prostitution, and to the providing and improving of therapy But there must still be something lacking in the program if the disease has not been eliminated but increases One is forced to stop and consider whether there may be more basic causes for the evil than have been recognized and dealt with Certainly few people wish to become diseased or wish to spread the infection, and yet the disease persists The readiness of the public to leave all effort and responsibility to the specialized authorities is certainly a large factor in the problem But it is evident that a more positive element than this passivity must be opposing their efforts

The real problem, of course, arises from the sex drive of men and women both One cannot attribute the cause to either of the sexes alone since more and more women are adopting the aspects, the attitudes, the appetites, and the habits of men If there were no sex activity at all, venereal disease, of course, would quickly disappear Or, even if all sex activity were confined to marriage partners who had been passed as uninfected, there would, in a short time, be no problem The fact that the disease persists rests upon the fact that sex contact exists outside of these certified marriages The problem before the social hygienist then is really reduced to one of social morality

But what is a young man, strong and vigorous as our good food and healthful living have made him, to do when the deep urge toward sex expression arises? The ideal held up by the churches and by the moralists is complete con-

tinence before marriage and subsequent strict fidelity. The assumption seems to be that the physical pressure can be relieved by emission dreams and the emotional by sublimation in sports or intellectual or creative pursuits. I have no doubt that for some young men this is possible but in reality their number is few.

Our society may uphold in theory the necessity for confining sex activity to marriage but actually marriage today is increasingly difficult to achieve. Our standard of living is such that the ability to earn enough to support a family is slow in coming. There are many years between the onset of puberty and the time when the average young man can start to maintain a family. As a matter of fact, we have even set up a barrier to early marriage by requiring the consent of parents for a boy under 21 to marry. For at least seven years, at a time when the sex urge is very strong and self-control imperfect, we deny him the outlet which we hold up as the only suitable one. We have raised the age at which a boy can leave school and start earning a living, thus delaying his progress toward the point of being able to support a family. All of these measures may be good in themselves but they add to the difficulty of the problem that the social hygienist is trying to deal with.

If we assume that complete continence is possible and desirable, we should logically try to lessen the stimulation toward activity. Actually, we are not a people who take self-denial easily. Even during the war with the arousal of patriotism, the rationing system was far from effective. We Americans had been brought up on the principle of abundance, of the possibility of getting whatever we want, and we do not take easily to prohibitions. Our method of bringing up children is an extremely indulgent one and parents find it hard to deny any of their children's wishes for fear of losing their love. There is even an attitude in education that children must not learn failure but must be promoted in school, whether or not they have earned the promotion by attending to their studies. All of this is a poor preparation for a boy or a girl to deny himself the satisfaction of his sexual appetite. Moreover, we have made something of a cult of love and leading one's own life regardless of consequences. Directly or indirectly, this attitude is presented in the current moving pictures, stories, and radio programs. The sexually stimulating pictures of pin-up girls were considered almost a necessity for the boys in service. The fashions of dress, the dances, even the advertisements in the subways are sexually suggestive. With little capacity for self-denial and with stimulating surroundings, is it likely that young people will develop self-control and be continent?

In all other respects our society encourages achievement at any cost, and without delay. Naturally, this carries over to the field of sex. One might expect fear to serve as a deterrent. However, the influence of the old religion with ideas of eternal punishment has dwindled away. It has been replaced commonly by a casual attitude that one lives only once and has a right to enjoy life. We have developed such confidence in the scientist who can miraculously save us from the consequences of our neglect that we have lost the fear of punishment by nature as well as by God. In such a general situation the old ideal of continence before marriage lingers on in but few places. To tell a young man that the solution of his sex problem before marriage is complete suppression of his desire is to mark oneself as out of step with the times.

For the idealistic young man with inadequate self-control, autoeroticism still plays a role. Rarely does one find a boy now who really believes that he injures himself by masturbation. The old type of literature which foretold dire consequences has largely disappeared. It has been replaced by statements that auto-eroticism is a normal stage in the development of a boy which even has the value of making him accept sex into his life. However, solitary enjoyment loses its value to the average boy who sees others more adventurous and who is reaching out toward reality rather than fantasy. It is even possible that the boy who spends years in fantasizing sex relations may be handicapped in a successful heterosexual adjustment, finding reality less satisfying than fantasy. It is true that by confining his sex activity to himself he is escaping the possibility of venereal disease but again one can question which is the greater evil. Can we conscientiously encourage masturbation as a solution?

With the elimination of prostitution, it is probably more common for boys today to express their sex desires with a girl of their own class and age, even to the extent of having a "steady girl friend." This type of pseudomarrriage, which provides the privileges without the responsibilities of marriage, certainly is a threat to family formation. It is true that the former attitude of concern about the virginity of a bride has practically disappeared and many of these relationships lead to legal marriage, especially if pregnancy occurs. However, a girl so easily acquired does not always have great value and with the comparative ease of divorce this custom perhaps contributes to the growing instability of marriages. Moreover, it is certainly true that venereal disease is spread through this custom, although perhaps the official reports can never be as accurate as those about prostitutes whom the boy has no

need to protect It seems very doubtful that society would favor this solution for the problem of young men

Another practice which is becoming more prevalent than perhaps society in general recognizes is homosexuality This may commonly start as a casual adventure rather than as a deep emotional attachment but the freedom from consequences and the increasing opportunities make it a growing competitor with casual heterosexuality Certainly this is as great a potential source of the spread of venereal disease as relations between men and women Unfortunately, there is still so much social disapproval of the practice, however, that the man who acquires the disease in this way is unlikely to acknowledge it, and honestly report the man who is spreading the disease

Prostitution has been widely banned and even though it still exists, it has lost in popularity It still furnishes an outlet for some of the cruder young men and those who want to divorce their sex life from emotion Actually, the need to go to a prostitute has almost the connotation of failure to achieve a girl without pay Moreover, there is in all men a strong desire for conquest and a sense of competition which make prostitution less attractive than a personal relationship Even without repressive measures, prostitution might gradually disappear

I realize that I am giving a rather pessimistic picture of the present attitude of young people toward sex If, however, we wish to deal effectively with a sex problem, we cannot blind ourselves to reality Boys and girls, men and women with strong, normal sex drives, with little experience in self-denial, with lessening fear of the consequences of venereal disease because of its treatability, with little religious fear of punishment for sin, with marriage hard to achieve and no longer a real sacrament, with a cynical opinion of the stability of family life, with constant stimulation from their surroundings—such young people are going to continue to risk getting venereal disease despite having information, despite eradication of prostitution, and despite improvement of treatment facilities Any effective campaign must be adjusted to the basic facts

In the face of such obstacles, it is not easy to think of additions to the social hygiene program that might be effective If we take it for granted that premarital and extramarital sex relations are for the present widespread, it would seem desirable to face openly this fact and to think in

terms of improving physical protection against disease, of making prophylaxis more effective and more easily available It is true that prophylactic stations for men in military service were not always used and there might be the same resistance to using them that shows in the use of public clinics It is conceivable, however, that ways could be worked out to make the use of prophylactics more acceptable and more widespread If this were done, one would have to recognize that it is making extramarital sex activity even more free from consequences and perhaps more common The evils of this would have to be weighed against the possibility of eliminating venereal disease And any such program could not be rightly started upon without serious thought

Although it would be difficult to accomplish, it is conceivable that there might be some lessening of the constant external stimulation toward sex excitement Some efforts have been made to censor the moving pictures but, as one observes them, it is evident that the basic attitude toward sex has only been more subtly presented rather than changed Certainly it has been difficult to raise public opinion against prostitution and it might be even more so to try to suppress the erotic literature and pictures which we come across everywhere Nevertheless, I believe that there is more stimulation from this source now than from prostitution and it might well merit the attention of the social hygienist

Going even further afield, the social hygiene program might involve increasing attention to the study of the factors that make early marriages difficult to achieve and to sustain More stress upon the responsibility of each individual rather than upon the specialist, with its relation to the total picture of the need for accepting responsibility in a free society, might, in the long run, yield some results

In general, however, no program can be effective that disregards these deeper basic drives in people The essential tendency toward self-indulgence in human nature and the fact that generations succeed each other so rapidly, force us to recognize that no program can remain static but must be constantly adjusted to changing social attitudes But until the general public is willing to protect the community before indulging themselves, the problem of venereal disease will persist

14 Washington Square

SAFETY FIRST

Doctor "We're trying to check the epidemic in the village Are you taking precautionary measures to prevent the spread of contagion?"

Housewife "Oh yes indeed, doctor We've even bought a sanitary cup, and we all drink from it"—*Canadian Doctor, Sept., 1945*

THE HEMORRHOIDAL-PROSTATIC-IMPOTENCE SYNDROME

ALFRED J. CANTOR, M.D., Flushing, New York

IN THIS brief paper it will be my purpose to present 3 typical cases, in a total series of 37, demonstrating an apparent relationship between sexual impotence, prostatic hypertrophy, and internal hemorrhoids. No definite conclusions should be drawn from so small a series of cases, and none will be advanced. Certain inferences, however, might reasonably be in evidence, and on the basis of inference, an anatomicopathologic theory will be offered as a tentative and probable explanation of the facts.

One of the cases to be presented was referred for the injection treatment of hemorrhoids, the effect upon a coexisting impotence being purely incidental to treatment of the hemorrhoids. The second case was referred by the first patient, peculiarly enough, for impotence. This patient asked to be treated for his impotence by the same rectal injections used for his friend! The third case was complicated by a rectal adenoma but revealed the same hemorrhoidal prostatic-impotence syndrome.

Case Reports

Case 1—M. J., a contractor 45 years of age, twice-married, presented himself with chief complaints of rectal bleeding while straining at stool, and constipation, the former of six months' duration, and the latter "all his life." Further history revealed nocturia, four times each night; mild difficulty of micturition, especially in starting the stream, and moderate frequency. No mention was made of sexual impotence at this time.

Physical examination revealed a well-developed, well-nourished male. The only relevant positive findings were a complete ring of internal hemorrhoids, none pedunculated, and all of moderate size, none of which prolapsed on straining. The prostate was moderately enlarged, slightly tender, and soft throughout.

Therapy consisted of ten weekly treatments with quinine and urea hydrochloride, injecting two quadrants each week, according to the technique outlined in previous writings.¹ Rectal bleeding ceased quickly and the patient was discharged with instructions to return in two months.

At the time of return the patient jubilantly announced that not only had rectal bleeding ceased but also the nocturia and difficulty of micturition. He further volunteered that for the past month there had been a definite improvement both in libido and in the quality of erections. As he phrased it, "I have become five years younger sexually." Rectal examination revealed the prostate to be the same size as at the initial examination and slightly

tender, as before, but it seemed less soft in its consistency. No further hemorrhoidal injections were indicated. A further recheck in six months revealed a maintenance of this status.

Case 2—R. L., an engineer 47 years of age (an employee of M. J., above) presented himself with a chief complaint of impotence and requested "the same rectal injections used for his friend." The impotence was of two years' duration and had never been investigated. He attributed it to his over-indulgence in alcohol, two to three pints of whiskey a day on many occasions. Nocturia, frequency, and burning on urination were noted.

On physical examination, I found a well-developed, well-nourished man of huge bulk and stature—weight 203 pounds, height 6 feet 4 inches. There was no evidence of cirrhosis of the liver. The prostate gland was found to be definitely enlarged and boggy. The secretion obtained on massage contained few pus cells. Although there were no rectal symptoms, several moderate-sized internal hemorrhoids, and one combined anorectal hemorrhoid were found.

I informed the patient of these findings and advised operation rather than injection treatment. I warned him that treatment of the hemorrhoids by injections would probably have little or no effect upon his sexual condition. However, he insisted upon the gamble, and six weekly injections of quinine and urea hydrochloride were given. Urinary antiseptics were also prescribed.

Upon re-examination, two months later, subsequent to the completion of treatments, the prostate was found to be slightly decreased in size, although still soft, and the combined anorectal hemorrhoid required further injection. The nocturia, frequency, and dysuria had ceased almost completely, but the sexual status was unchanged. The four-month recheck revealed an identical rectal status, but a surprisingly changed sexual status. Sexual desire, sturdy erections and ejaculations were elaborately described in great detail, with both the mathematic precision and picturesque language of an engineer.

Case 3—W. P., a garage mechanic, 52 years of age, gave a history of increasing rectal bleeding, constipation and straining at stool with protrusion of a "rounded mass" from the rectum easily replaced by the fingers, all of six months' duration.

Also noted were a history of one acute episode of urinary retention two years previously, subsequent nocturia and dysuria, several episodes requiring introduction of a catheter, and present difficulty in completely emptying the bladder. Sexual power and desire had rapidly declined since the first acute episode. The patient presented himself for treatment of the proctologic conditions.

Physical examination was irrelevant aside from the proctoscopic and rectal digital investigations. The prostate was markedly protuberant, tender, and

¹ Cantor, Alfred J. Ambulatory Proctology. New York City: Paul B. Hoeber Inc. 1946, p. 172.

boggy Rectal prolapse, which carried down a sessile rectal adenoma situated on the posterior rectal wall, was demonstrated. Several small internal hemorrhoids were noted.

Treatment consisted of surgical excision of the adenoma, followed by fulguration of its base. Two weeks later the internal hemorrhoids were injected with quinine and urea hydrochloride, and one month thereafter injections of the same solution were introduced in the treatment of the prolapsus recti.

At the present time, four months later, rectal symptoms have entirely ceased, rectal prolapse has not recurred, the prostate is definitely smaller and firmer, urinary symptoms are slight, and, most remarkable of all, sexual power and desire have greatly increased.

Comment

To draw definite conclusions from a small series of 37 cases would be unwise and unwarranted. However, to overlook the inferences of these cases would be equally unwise. In each case there was evident an apparent relationship between hemorrhoids, prostatic hypertrophy, and sexual impotence. At least we may say that subsequent to treatment of the hemorrhoids there resulted an apparently consequential decrease in size of a previously enlarged prostate, and an improvement in a previously diminished sexual vigor.

It is difficult to account for the changes on an anatomic and physiologic basis. We may assume, however, that the close relationship of the blood supply of the prostate gland and of the rectum is an important factor. It would seem that with the obliteration of the rectal varices a previously passively congested prostate gland is relieved of its congestion.

It is well known that the pudendal plexus of veins constitutes the anterior part of the prostatic

plexus. The venae comites of the internal pudendal artery arise in the plexus, and these venae comites, before proceeding on to become a single internal pudendal vein, receive veins from the inferior hemorrhoidal. The inferior hemorrhoidal veins are intimately connected with the internal hemorrhoidal plexus, through the terminal veins of the columnae rectales. This plexus, in turn, leads into the middle hemorrhoidal vein, which empties into the hypogastric vein. The inferior hemorrhoidal and internal pudendal veins are also tributaries of the hypogastric vein.

There must be an equally close lymphatic interrelationship between the prostate gland and the rectal wall.

It would seem reasonable to conjecture the possibility of passive vascular congestion (and perhaps associated lymphatic congestion of the prostate gland), due to the varicose reservoir supplied by hemorrhoids. If this is so, then it is equally reasonable to suppose that with removal of this varicose reservoir a cessation of passive vascular prostatic congestion might result. This may explain the improved prostatic condition observed in the above cases on re-examination, after hemorrhoidal injections. The improved sexual status may reflexly, directly, or psychically (or in all three manners combined) be the next link in the hypothetic chain. Similar results have been observed in 23 surgically treated cases. Further observations, and analyses of the follow-up course of both injection and surgical cases will aid in evaluation of the hemorrhoidal-prostatic-impotence syndrome.

No conclusions are offered. I merely submit for consideration the probability of a hemorrhoidal-prostatic-impotence syndrome.

VETERANS' RIGHTS

"Each physician should have a major hospital—that is, one to which he wishes to attach himself more intimately and do most of his work."

"A properly organized medical staff will not give advantages to any individual or group of physicians, or discriminate against the young physician properly qualified and competent, but will insure desirable supervision of all clinical work done in the institution."

The above excerpts from the Manual of Hospital Standardization, published by the American College of Surgeons, plainly lays down the principles that every physician should have a hospital to work in and the privilege of doing any procedure of which he is capable.

These principles are vital at the present time as they affect our returned veterans, especially the younger men who did not have an opportunity to

make a hospital affiliation before they went into service.

These veterans will return to find that when they do have hospital cases, vacant beds are at a premium and that unless they were previously members of some hospital staff, staff positions are frozen for the duration. In addition, many of them have been in no position to show their ability as most of their experience will have been in the armed services.

Every hospital staff should immediately consider this problem so that we who stayed behind may show our appreciation to those who went, with something besides empty words and a pat on the back. Let us work to see to it that every physician, especially the returned veteran, has a place to work and the privilege of working.—W B Harm, M D, *Detroit Medical News*, Nov 12, 1945

ELECTROCARDIOGRAPHIC EVIDENCE OF MYOCARDIAL DEGENERATION IN AN AMERICAN PRISONER OF WAR FOLLOWING UNDUE PHYSICAL STRESS AND OTHER FACTORS

M D MIERAS, Capt., (MC), AUS, and R L ZIMMERMAN, First Lt., (MC) AUS

(From the Station Hospital Fort Totten, New York)

This patient was a 24-year-old AAF gunner who went overseas in May, 1943, parachuted down in February, 1944 over Germany unharmed except for the loss of a few teeth, remaining a prisoner of war for fifteen months until he was liberated by the Russians in May 1945. During his internment he was subjected on several occasions to severe exertion (at one time he was forced to run with full equipment for several miles at bayonet point and on another occasion was forced to march about 750 miles in six weeks). The food was always inadequate. Red Cross packages reaching him only at infrequent intervals. His dietary intake averaged about one fourth of one Red Cross parcel content per week plus a daily intake of one seventh of a loaf of German black war bread 50 Gm of horse dog or ox meat, three medium-sized potatoes, carrots, sauerkraut and cabbage irregularly. On this regime he lost a total of 45 pounds.

Following liberation, the patient drank heavily for a few days. When he arrived in the United States he went on a "drinking bout" which lasted for fifty days of his furlough time, during which he averaged about one quart of liquor daily.

Five days prior to admission, on August 6, 1945 the patient was seized with a sharp, nonradiating, subternal pain, occurring at rest. His civilian doctor took an electrocardiogram and told him he had a "nervous condition." The pain lasted two days and disappeared spontaneously without medication. On August 11, 1945, he was hospitalized at Station Hospital, Fort Totten, New York where a review of his previous electrocardiogram revealed inversion of T₁ and T₂ and diphasic T₃. His civilian doctor had not given him digitalis.

Fig 1

Fig 2

Upon admission here he had no complaints but gave the history of the pain described above which had occurred five days before and lasted for two days. He had never had rheumatic fever. In fact, his past history was free of any serious illness except for an attack of "yellow jaundice" in 1943 from which he recovered after fifteen days of hospitalization.

Physical examination revealed a well-nourished man having no enlargement of the heart clinically or roentgenologically. There were no murmurs or arrhythmias and the heart sounds were of good quality. The lungs were clear, liver was not palpable. There was no edema. The remainder of the examination was negative and there was no clinical evidence of avitaminosis. The patient did not show weight loss described in the history above, having been on normal rations since his liberation.

Laboratory findings on admission were as follows: white blood count, 5,000, 60 per cent polymorphonuclears, sedimentation rate, 5 mm, urine normal. One week after admission the white blood count was 10,400, with 72 per cent polymorphonuclears, and the sedimentation rate was 14 mm. Kahn test was negative. Electrocardiogram taken on August 11, 1945, revealed inversion of T waves in leads I and 2, diphasic T in lead 3, and was identical with the electrocardiogram taken by his civilian doctor, a copy of which was brought to Fort Totten for comparison (Fig 1). A second electrocardiogram on August 14, 1945, revealed more inversion of the T wave in lead 3 (Fig 2).

Starting August 20, 1945, the patient was given a high vitamin diet, 100 mg of thiamine chloride intravenously and six multivitamin capsules daily. No other medication was given. The patient was ambulatory but stayed most of the time in his ward.

FIG 3

FIG 4

He had had no alcoholic beverages since his admission to the hospital.

After seven days of this therapy, the third electrocardiogram, taken on August 27, 1945, demonstrated that T_2 and T_3 were beginning to lose their negativity (Fig 3). The same regimen of thiamine chloride intravenously and multivitamin capsules by mouth was maintained and the electrocardiogram taken on September 4, 1945, showed T waves in the standard leads almost normal (Fig 4). The last electrocardiogram, on September 18, 1945, revealed a normal tracing (Fig 5).

FIG 5

Comment

This case is being presented to demonstrate electrocardiographic evidence of myocardial degeneration in a soldier who had been a prisoner of war in Germany subjected to undue physical hardship, marked malnutrition, along with heavy ingestion of alcohol following his liberation. With no treatment other than rest, high vitamin diet, thiamine chloride intravenously, and vitamins by mouth, there was brought about a complete reversal of the negativity of the T waves in the standard leads in a period of thirty days.

We were unable to demonstrate evidence of rheumatic heart disease or other conditions which might have produced these electrocardiographic changes. Even though he complained of substernal pain, clinically, and electrocardiographically, the patient did not present the clinical entity of a coronary lesion.

We are presenting this case on the presumption that the conditions under which this prisoner of war lived while in Germany may have produced some myocardial changes which remained unchanged until high vitamin regimen was instituted, and that the combination of avitaminosis, physical stress, and ingestion of large amounts of alcohol produced the myocardial degeneration.

It is felt that many returnees who have been prisoners of war and may have been subjected to similar experiences can be observed for possible latent myocardial degeneration similar to that described above.

Man alone has the gift of reason, yet he alone behaves in a manner that seems illogical and irrational.—*Clinical Medicine*, March, 1946

MEDICAL SERVICES AND THE VETERANS ADMINISTRATION*

EDMUND EASTWOOD, M.D.

(Director, Outpatient Service, Department of Medicine and Surgery, Veterans Administration)

WHEN General Hawley took over the Medical Service of the Veterans Administration last August, he established as his long-range objective, "A Medical Service Second to None"

An easy thing to say, "a medical service second to none," but what does it mean? It means a many-faceted goal, difficult to attain

In terms of medicine and surgery, it means that in all of the special branches of its science and art, the Veterans Administration will provide a service that meets the highest standards set for each

In terms of physical equipment, it means hospital beds, outpatient clinics, modern, up-to-date scientific equipment

In terms of personnel, it means that adequate staffs of qualified personnel in all of the professional, subprofessional, and nonprofessional categories will be in those hospitals and outpatient clinics to serve the veteran

In terms of professional cooperation, it means that the best specialists, physicians, and dentists in civilian practice in the country will be serving the Veterans Administration on a fee-for-service, part-time, or consultant basis

In terms of education, it means that doctors will be training for Specialty Board examinations in residencies established at Veterans Administration hospitals, while also giving care to veterans

In terms of the Congress, it means that our legislators will be satisfied that the funds they have appropriated for the care and treatment of eligible veterans are being wisely administered for benefit of veterans.

In terms of the general public, it means that those who have loved ones eligible for medical or hospital care or treatment will be getting that care or treatment

In terms of sick or disabled veterans, it means the ultimate in physical or mental rehabilitation that is possible in each individual case

You have heard the goals. Now let us see how far along the road toward these goals the Veterans Administration has come.

Although the broad, overall objective for the general medical, the general surgical, the tuberculosis, and the neuropsychiatric services is the same, the procedures for reaching that goal vary

with each service. However, the general pattern of procedure is sufficiently similar to permit the citing of one, in order to give you a glimpse of them all

Let us take a look, for instance, at the General Surgical Service. The goal is a surgical service that in every way meets the standard for general surgery that has been set by the American College of Surgeons

It is inconceivable that General Hawley could accomplish this alone. So, he has appointed a Board of Consultants, composed of a representative from each of the twelve surgical specialties, to assist him

They, in turn, have appointed a representative in each of the twelve surgical specialties to advise and work with the Branch Medical Directors in the Veterans Administration Branch Offices. These Branch Office Consultant groups are responsible for surveying and evaluating the surgical service in each Veterans Administration hospital in the Branch Office area, and making such changes, as may be required, to bring the surgical service in these hospitals up to the standard

It should be remembered that the problem is twofold, because certain Veterans Administration hospitals have, or will have, residency training programs, while others, too far removed from medical centers to make cooperation feasible, will have no residency program.

At the present time, all of the Branch Office Surgical Consultants have been appointed and are beginning to survey the hospitals within their areas. The hospitals with residency programs, either under way or in the formative stage, will be the last to be surveyed, as the responsibility for the standard of residency is now resting with the medical schools that are engaged in establishing teaching programs at our hospitals

It is self-evident, of course, that no hospital program can succeed without hospital beds

In December, 1941, the Veterans Administration was operating 92 hospitals in three main clinical types: 50 general medical and surgical, 30 neuropsychiatric, and 12 tuberculosis—a total of 72,000 beds. In addition, there were 12 Veterans Administration homes with approxi-

General Hawley, chief medical director of the Veterans Administration, and Dr. J. C. Harding, assistant medical director, regret that owing to circumstances beyond their control neither was able to be in New York to address the meeting in person.

* Delivered at the Banquet of the 140th Annual Meeting of the Medical Society of the State of New York May 1, 1946.

mately 19,000 beds for the use of ex-servicemen and -women, permanently disabled to a degree which prevented them from following any gainful occupation, yet, whose disabilities had reached a static condition not requiring actual hospital care

As the war progressed, rapid and heavy demands for more hospital beds had to be met. The Veterans Administration attempted to solve the immediate problem by installing, in existing hospitals, emergency or expansion beds, over and above normal standard capacity. By V-J Day, 11,000 expansion beds were added, increasing the capacity to 83,000 beds. Use of expansion beds will be discontinued when new units to existing hospitals or new hospitals with sufficient capacity to care for the patient-load, now provided for under the authorized emergency bed allocation, can be acquired.

Hospital expansion plans call for the construction of new hospitals and the transfer of others from the Army and Navy. Under the present building program, the Veterans Administration will add 74 permanent hospitals of all types, with a bed capacity of 52,110 beds. As of April 4, 1946, we had 101 hospitals with a total of 85,302 authorized beds.

In addition to the construction and acquisition of new Veterans Administration hospitals, contracts are being let for the use of beds in civilian hospitals and other Federal hospitals when these are in surplus, over and above the needs of the respective community or service, for it is not the purpose of the Veterans Administration to hamper civilian hospitalization. We hope soon to have 20,000 contractual civilian hospital beds, although, as of February 26, 1946, only approximately 9,000 such beds were under contract. The exact total of beds that ultimately will be available in civilian hospitals is not known. At the present time, hospital associations in Kansas, Michigan, Oregon, and North Carolina have signed contracts and 36 other States are negotiating, either directly or indirectly, for participation in this program.

The goal for our Outpatient Service does not differ in the standard of treatment from that of the hospitals. But the problem is complicated because of the tremendous number of physical or mental examinations, which must be given on an outpatient basis. Examinations are required to determine the need for medical treatment and care, for the adjudication of claims, to determine need for hospitalization, to provide records from which percentage of disability may be evaluated for compensation and pension purposes. It is estimated that during 1947, more than 2,000,000 veterans will require complete physical or mental examinations.

With a potential veteran population of more than fifteen million from World War II, it readily can be seen that there will never be enough doctors in the Veterans Administration to give the necessary examinations. Nor will there be enough Veterans Administration outpatient clinics. General Hawley has appealed to civilian doctors for help in solving this major problem.

General Hawley has received magnificent response to his appeal, and several State plans for outpatient examinations and treatment have been worked out.

The Kansas State Plan is a notable example of this cooperation, and will work in the following manner.

The Kansas State Medical Society has submitted a list of their qualified members, who desire to render service to the Veterans Administration, in accordance with a predetermined schedule of fees. From this list, those vouched for by the Society are appointed as Veterans Administration physicians on a fee basis and their work for the Veterans Administration will be supervised by the Society in the various zones throughout the State. Medical service will be given to the veteran by the nearest qualified physician, under authority granted by the Veterans Administration representative designated for that purpose, and fees for treatments will be paid by our agency to the physician who renders the service. For convenience in operating this plan, the designated Veterans Administration representative is located adjacent to the office of the Kansas State Medical Society in Topeka.

One of General Bradley's and General Hawley's first objectives has been attained—the passage of legislation to enable them to establish educational and professional attractions for the finest caliber of hospital personnel and to permit them to employ doctors, dentists, and nurses without reference to the rules and regulations of the United States Civil Service Commission.

Public Law No. 293, of the Seventy-Ninth Congress, created a Department of Medicine and Surgery in the Veterans Administration, effective January 3, 1946. Since then, educational programs in the form of residencies have been established for doctors, and standards, independent of the Civil Service Commission, have been set for personnel in what are called the Auxiliary Services, that is, dietetics, social service, etc.

Long-range estimates of personnel needs are, to mention a few, 7,000 full-time Veterans Administration physicians, 750 dentists, and 30,000 nurses. Although still a long way from meeting these goals, the Veterans Administration has added hundreds of full-time doctors to its staff.

VETERANS ADMINISTRATION BEFORE REORGANIZATION

With Control of 97 Hospitals and 53 Regional Offices
Centered in Washington

FIG 1

since the first of the year. A net gain of about 100 nurses a week is helping to alleviate, although not meeting, our need for nurses and the Dental Service reports more applications on hand than it will have positions to fill in the next eighteen months.

When General Hawley said, "Without the assistance of Class A medical schools, it would be impossible for the Veterans Administration to operate its present hospitals at a satisfactory standard," he had reference to the residency program in process of establishment at Veterans Administration hospitals that are located near medical schools or teaching centers, and the selection of physicians who are teachers in Class A medical schools or outstanding specialists to act as consultants on a part-time or fee basis.

The ultimate goal of these programs is 1,000 full time resident physicians and 500 part-time attending consultants.

On April 18, 1946, 63 out of the 77 Class A medical schools in the United States were co-operating in the residency program, 224 resident physicians were on full time duty in 12 Veterans Administration hospitals and 536 consultants and attending specialists were serving 17 Veterans Administration hospitals. For detailed information about the residency or consultant programs, doctors should consult the Dean of any Class A medical school.

One of the most interesting and important

phases of the General Hawley program is the medical rehabilitation of patients in Veterans Administration hospitals. The goal for this service is the ultimate physical and mental rehabilitation possible in each individual case. It is an interesting challenge because of the necessity of meeting the special problems involved in the rehabilitation of the tuberculous patient, the neuropsychiatric patient, the amputee or otherwise disabled, and the paraplegic, or spinal cord cases.

Because there had been no comparable program in the Veterans Administration, a completely new section or service had to be created. Today, we have come a long way down the road. The Medical Rehabilitation Service has been established. Field personnel is just beginning to be appointed, but the Medical Rehabilitation Service already has become an integral part of the medical program.

Of major importance to the whole program of the Veterans Administration is General Bradley's decentralization plan for streamlining the operations of all of the functions of the agency.

Where, previously, all activities were administered from Washington, under decentralization they will be administered on an area basis from 13 Branches of Central Office, with headquarters in each of what are, roughly the 13 Civil Service Districts throughout the country.

There has not been sufficient time, as yet, to

VETERANS ADMINISTRATION AFTER REORGANIZATION

With Control and Supervision in 13 Branch Offices to Break the Washington Bottleneck

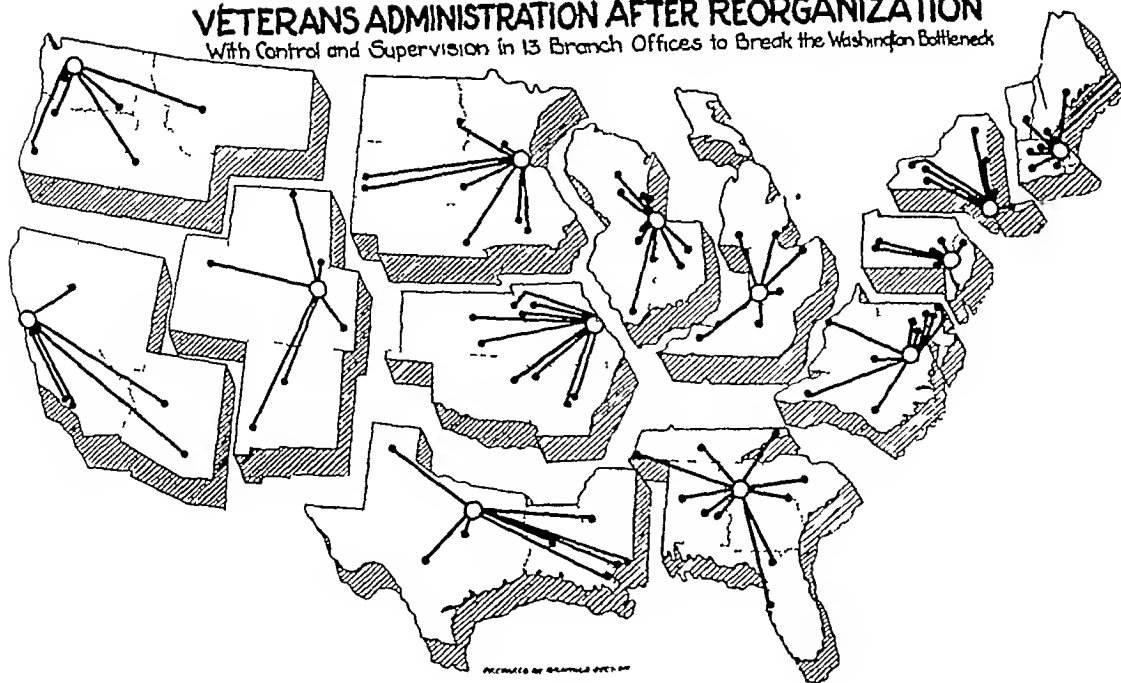

FIG 2

determine the effectiveness of decentralization, but the 13 Veterans Administration Branch Offices are open and began to function, officially, as of April 1, 1946

General Hawley is sincere in his praise of the American doctor, both individually and collectively. He has repeatedly said, "There is no substitute for a good doctor." And he means it.

In an address before the House of Delegates of the American Medical Association, General Hawley recognized and paid tribute to the medical teaching centers of this country. He recognized them as the source from which the American doctor has drawn, and is drawing, his medical knowledge and skill—knowledge and skill so gloriously reflected in the saving of a higher per-

centage of wounded during World War II than has ever been possible in the whole history of previous warfare.

Today, General Hawley is leaning heavily upon the qualified American doctor engaged in civilian practice. He needs his help in giving outpatient treatment. He is dependent upon him for assistance in Veterans Administration hospitals.

He needs the help of the organized State Medical Societies in encouraging communities where there are unused hospital beds to make these beds available to the Veterans Administration. In that, he needs your help in providing for veterans "A Medical Service Second to None."

OSLER SAID IT

The well-conducted medical society should represent a clearing-house, in which every physician of the district would receive his intellectual rating, and in which he could find out his professional assets and liabilities. We doctors do not "take stock" often enough, are very apt to carry on our shelves stale, out-of-date goods. The society helps to keep a man "up to the times," and enables him to

renew his mental shop with the latest wares. Rightly used, it may be a touchstone to which he can bring his experiences to the test and save him from falling into the rut of a few sequences. It keeps his mind open and receptive, and counteracts that tendency to premature senility which is apt to overtake a man who lives in a routine.—Sir William Osler

THE PHYSICIAN IN THE PATIENT-PHYSICIAN RELATIONSHIP*

ALPHONSE M. SCHWITALLA, S.J.

(Dean, St. Louis University School of Medicine, President, Catholic Hospital Association)

THE patient-physician relationship is fundamental in medical practice. This almost axiomatic truism would seem to be so palpably obvious as to make redundant, futile, and even platitudinous, any repetition of emphasis or re-statement. Yet, true as the statement seems, its translation from mere verbal formulation is a challenge to the sincerity, the competence, and the character of the physician. Today, it is true that even some physicians will pay lip service to the principle but will in their actual practice not only completely disregard the principle but will even deny its validity in medical practice.

Yet, it must be insisted that this principle is fundamental, fundamental in the ethical relationships between the patient and his doctor in so far as this principle establishes the reciprocal privileges and obligations of two individuals, fundamental in the professional relationships between the patient and his doctor in so far as this principle establishes the dependence of the patient with his biologic and psychologic needs, on the one hand, and the physician with his capacity and his willingness to meet those needs, on the other hand, fundamental in the profoundly human relationships between the patient and his doctor arising from the interplay of thoughts, emotions, and feelings emerging from sufferings and anxieties, on the one hand, and the readiness to apply remedial measures and physical, as well as psychologic sedation on the other hand. Medical practice obviously would not be medical practice if there were only patients without physicians or only physicians without patients, if there were only unmet needs or unapplied capacities, if there were only scientific truths instead of human needs to which these truths could be applied, or if there were only human needs without the competence to meet them. It is the patient and the physician who make the relationship possible and lay the foundation stone for the superstructure of the most intimate, the most searching, and the most extensive relationship between the practitioner of medicine and the beneficiary of that practice. It is the foundation of medical ethics, the basic reason for the maintenance of competence in the physician, the basic reason also for the demand of the art of medical practice that the physician must be a man of character and integrity beside being a man of knowledge.

The relationship is obviously a relationship between two human beings. Like all relationships, it is an explicit or implicit contract. The relationship is founded on a *quid pro quo* on either side. It involves a giving and a taking on both sides, it demands clearness of understanding, of obligations and responsibilities on both sides, as well as of benefits and privileges on both sides, it requires certain functions on both sides, certain mental and emotional attitudes. While, therefore, the contracting parties in the relationship are on a one-to-one basis, patient and physician being equally the contractors, nevertheless, with reference to ethical demands, the two cannot be equal for the patient is in need of something which the physician can help him to secure, not of something which the physician can give. The physician does not give the patient health. He aids the patient's organism in the readjustment which results in health, but that aid is something so much beyond anything for which the patient can render a commensurate *quid pro quo* that the patient is utterly incapable of remunerating the physician, even approximately adequately for the intangible but emphatically real benefits which the aid of the physician has effected within the patient's organism or his personality. In other words, the physician does not give health for a dollar, the patient does not pay a dollar for his health, but the physician assists the human organism of the patient through the procedures suggested by the physician's competence and his self-dedication to his vocation to a restoration of the equilibrium between the organism and the environment or to a restoration of that internal equilibrium between the diverse parts or functions of the organism. Both of these restorations we designate as restorations to health, for which aid the patient gives or may give a token payment to the physician, but he must give the physician his appreciation, gratitude, and acknowledgment of an obligation which are the physician's only real remunerations.

If this is a valid and an approximately correct analysis of the relation between patient and physician, we may well raise two fundamental questions. First, what does the patient-physician relationship demand of the physician, and second, what does the patient-physician relationship demand of the patient? The answer to both of these questions taken together, should throw the intense light of a complete revelation

* Delivered at the Banquet of the 140th Annual Meeting of the Medical Society of the State of New York, May 1 1946.

into the alleged or assumed vaguenesses and uncertainties in this patient-physician relationship. There will not be time, in the time at our disposal this evening, to attempt an answer to both of these questions. We shall, therefore, restrict our inquiry this evening to the discussion of the first of these questions and attempt such an answer as may be possible to the problem. What does the patient-physician relationship demand of the physician?

And first, let us raise a subquestion. What does the patient demand of the physician in this patient-physician relationship? If we have a clear understanding of this question, we may attempt an analysis of the further question of what society expects of the physician in the patient-physician relationship and finally, what the physician himself does or should or must demand of himself in this patient-physician relationship.

What does the patient demand of his physician in this patient-physician relationship? This question could be worded less abstractly in a vast variety of different ways depending largely on whom the patient is, whether he is an educated or a less well-educated individual, a wealthy man or a medically indigent individual, a discriminating man or a man who takes matters more or less for granted, a timid or bold, a fearful or trusting, a truth-loving or cynical man, in other words, a man who lives on the peaks or in the valleys of human emotions or, on the other hand, of a man who lives on the emotional flatlands and prairies of human experience. The question is asked, how does a person choose a doctor? And what is a good doctor? And why do I wish to choose my doctor? And why do I discriminate between my doctor and a consultant or a specialist? I am inclined to say that Dr Smith is my doctor, emphasizing the possessive pronoun but much less seldom do we hear the expression "Dr Jones is my laryngologist or my surgeon." We do say that "Dr Jones operated on me" or "I go to Dr Smith for my nose."

The question may again be worded in terms of popular discussions of the competence of physicians, the criteria and standards applied by the people as measures of professional efficiency. Or it may be reworded in terms of popular discussions of the physician's character as indicated by his approach to his patients or his discrimination between the different classes of his patients or his personal behavior toward his patients in his office or his examining room. The popular conversations about doctors are indicative of the demands which individuals or society make upon the physician.

It would seem that such thoughts as these might well have been suggested to those who would draft a national health bill since it is

through discussions of such questions as I am here raising that the feasibility or the impossibility would have been discovered of ever even approaching such concepts as the interchangeability of doctors as demanded by a panel system or the regulation of the numerical size of the physician's practice or the method of financial remuneration through a system of rules and regulations.

How do people judge a good doctor? It must be admitted that the question is extremely difficult to answer and still more difficult is it to answer the question how should people judge a good physician. Will I be misunderstood if I say, first of all, that there is little if any relationship between public action with reference to a doctor and the doctor's intrinsic worth? In other words, patients do not necessarily choose the objectively best doctor available to them anymore than people choose the objectively best banker or lawyer available to them. Reputation of physician, lawyer, or banker has much to do with his being chosen by many persons but that reputation may be established not on the basis of qualifications but on the basis of advertising, it may be established on the basis not of real professional competence but on the basis of popular appeal. Where crowds of patients flock, the crowds are apt to increase, where fees are large, they are apt to become still larger. Far be it from me to even imply that large fees are unworthy of the good doctor or that a large practice is indicative of relative inadequacy. The damnable thing about all this is that any criterion which is applied popularly in the judgment of the competence of a doctor may be indicative of sound worth just as it may be indicative of professional unworthiness. For the most part, however, this question, fortunately, need not be given a final answer because the true answer to the problem lies, it would seem, in quite a different direction.

Theoretically, and I would say even practically, there are no two doctors who are equally good for the same individual patient and to complete my thought, there are no two patients upon whom any one doctor is going to have precisely the same professional or personal effect. From a very reasonable point of view, we should have a teacher for each child and that fact is the real psychology as well as pedagogic educational reason why parents and, perhaps, particularly the mother should be the real teacher of the child. But when the child goes to school, we have a teacher teach a class of children because of the exigencies and limitations of society. We do not expect, however, that the teacher will have precisely the same effect upon each of her twenty-five or thirty children. We fondly hope

that the teacher will have at least a minimally beneficial effect upon that one of the children of her class upon whom she has the least effect. But with medical practice, there is no possibility of placing patients into classes. Each patient is a problem to himself not merely because disease entities manifest themselves in an almost infinite variety of variable presentations, but because the physician does not treat disease entities but treats rather an individual who has or thinks he has a disease, whatever the word disease might mean in this connection. That is the reason why there always must be a free choice of physicians by a patient and that is also the reason why there must always be a free choice of patients on the part of the physician.

My doctor is the doctor who is good for me. The fact that he is good for me with my special traits, my weaknesses, and strengths, does not mean at all that my doctor is good for you. How difficult it would be and practically impossible to bring this all home to the people at large, for the reply would be that the people are not familiar with a lot of doctors but, on the other hand, there still is in this analysis a depth of truth which one would hope might in the course of time through the processes of education be brought with greater emphasis to the attention of the lay mind.

Nevertheless, there still is an identifiable measure of truth in the expression "a good doctor." There is something corresponding to this phrase. It is the professional excellence of the doctor implying both competence and character, both scientific achievement and readiness to forget personal interests in his dedication to the interests of his patient. A good doctor is a doctor who lives up to the expectations of his profession even though he recognizes that standards set by an organization must necessarily be standards for the average and cannot be standards for the superior individual. He is a man who will value what his profession values as a general rule, a man who will not set his judgment against the judgment of his colleagues, a man who will be respectful to a colleague even though he must be critical of him. A good doctor will not spare himself, will not resent the requests of his patient or of the relative of the patient but will see in these requests the manifestations of deep human concern rather than of selfishness, and the indications of a profound anxiety arising from affection for the patient on the part of his dear ones rather than a morbid curiosity of a lay mind to understand a technical point.

How entirely different this thinking is from the thinking in the National Health Bill in which ostensibly the patient is given full freedom in the choice of his physician but must then choose

a physician who has qualified under the regulations and who has not as yet exceeded a quota of patient allotments for that particular area in which the patient is told that he may have any physician but then it is left to other authorities to determine when a patient should have a general practitioner or a consultant or a specialist, and when the patient is told that he has a freedom of choice of physician but then the pay for specialist or consultant or practitioner is regulated by rule, thus translating into an administrative problem the real needs and desires of the patient and subjecting these needs and desires to administrative and perhaps sometimes even coercive rule.

If the answer is made that it is only by such rules and regulations that we can have a national health program, let the subassumption be made as vigorous as possible: why must I have a national health program regulated by administrative enforcement if I must sacrifice some of my most profoundly valued and deeply rooted ethical ideals concerning the practice of medicine, and thereby sacrifice my independent responsibility for my health care and the health care of my dear ones?

And what does society expect of the physician in the patient-physician relationship? That society has a voice to which the medical profession must listen with reference to this matter no one will deny gainfully. On the other hand, the society's right to a voice in this matter must certainly be limited and must not come into conflict with the basic rights implied in the patient-physician individual relationship. What are society's rights and how do they modify the patient-physician relationship? This question raises the further one, upon what are the mutual rights of the patient-physician relationship founded? We have said that they are founded upon the contract but we have not defined the *quid pro quo* in the contract with sufficient definiteness to make such a definition the basis of further reasoning.

Now the *quid pro quo* is certainly not the stipend paid by the patient to the physician. This statement I regard as most essential in our thinking about this matter. It is for this reason that this code of medical ethics of the American Medical Association lay down as its first prescription that the service which the profession can render to humanity is the prime object of medicine while reward or financial gain is only a subordinate consideration. Needless to say, therefore, when the physician's desire for a reward comes into conflict with the good of the patient, it is always the latter that must take precedence. Proper ethics demands of the doctor that no consideration can ever be allowed

to come between himself and his patient if such a consideration is extrinsic to the welfare of the patient as the doctor seriously and sincerely in conscience understands the welfare of his patient. The first Code of Ethics of the American Medical Association, as far back as 1847, calls the doctor's attention to the necessity of having his mind and heart "imbued with the greatness of his mission, and the responsibility he habitually incurs in its discharge." But then, that first formulation of 1847 goes on to say "those obligations are the more deep and enduring, because there is no tribunal other than his conscience to adjudge penalties for carelessness or neglect."

Moreover, what really is the nature of the financial recompense which the patient gives to the physician and what is the nature of the financial gain. It is not and should not be a stipend in the sense that it is a payment of a stipulated sum fixed upon antecedent to the service to be rendered by the physician. I know that in certain quarters it is extremely unpopular to emphasize this point because, through a misconception of the fee schedule, the popular mind and in certain instances, even the professional man, has gained the impression that the fee schedule represents payments for certain services which imply medical responsibilities. No impression can be farther from the truth. In those medical societies that have best evaluated their own philosophy, the fee schedule is looked upon as a minimal demand of a physician for his services not as an obligatory fee, the understanding being that the physician in his relationship with the patient or with an agency which acts for the patient, will receive in recognition of his services at least the amount suggested in the fee schedule.

The reason for this interpretation lies in the nature of the payment to the physician. There is no common denominator between the services of the physician and the dollar. You cannot evaluate health nor life nor restoration to health, you cannot evaluate the intangibles associated with the health of a wife or child or of any of one's dependents. Therefore, it follows of necessity that any payment made to a physician for his services is in the nature of a token payment, no matter how large it is because even if it is a seemingly huge fee, the benefit of the personal self-sacrificing devotion to the physician bears no relationship whatsoever to even the largest financial fee. The payment to a physician, therefore, as a token payment, is a token of the patient's appreciation, gratitude, or the recognition of the physician's competence.

If this analysis again is correct, it would seem to follow that the more immediate are the rela-

tionships between the patient and the physician with reference to this payment, the more ethical are they. When, therefore, the benefits of the physician's services are received by the patient and the payment is made by some other agency extraneous to the two parties between whom the real contract exists, we are endangering the sanctity and the exclusiveness of the patient-physician relationship and we are exposing that relationship to the desecration of commercialism. We are degrading the services of the physician, the personal devotion of the doctor, his competence, the indescribable responsibility which he holds for life and limb, welfare and happiness of his patients, to purchasable commodities which surely, of their very nature, they are not and cannot be. We are thus materializing intangible goods, spiritual entities and we are bartering for coin the devotion and loyalty and confidential intimacy of the physician, together with the confidence and trust and the need for sympathy of the patient.

And this leads to the further consideration that an agency extrinsic to the patient-physician relationship cannot be a fit agent for a physician. It is for this reason that even the hospital, close as it is to the relationship, cannot adequately represent either the patient or the physician, least of all when the hospital, forgetful of its real nature as an aid to both the physician and the patient, presumes to become a corporate practitioner of medicine and recklessly enters into medical practice itself. I, frankly and straightforwardly, here wish to go on record, even though my interests are so wrapped up with the hospitals, as favoring the dissolution of any understandings or agreements or contracts between hospitals, on the one hand, and certain physician-specialists, on the other hand, which suggest commercialism rather than the ideals of which we are here speaking. And I deplore, with equal emphasis, the substitution of prepayment plans for hospital or medical care if in those prepayment plans there is bartered away the service of the radiologist or the laboratory pathologist or the anesthetist. Such paying agencies cannot escape criticism by saying that they are simply accepting the relationships that are presently existing between physicians and hospitals. The criticism should, however, fall not only upon the paying agency nor only upon the hospitals, but also upon those physicians who will lend themselves to these arrangements and who for the sake of avoiding inconveniences will simply follow the easier pathway.

There is, of course, much more to be said about all of this which cannot be touched upon briefly. In speaking of society's expectations of the physician in the patient-physician relationship, we

should have to touch upon the relations of the patient and physician to local, state, and federal governments, the obligations of the state in licensure, the protection of the people through not only licensure but through examination for competence, the possibility of licensure in the specialties and a vast number of subsidiary questions. The point I want to emphasize, however, even though I must omit these far-reaching discussions, is that complicated as all of this becomes in a complicated society, the obligations of the physician toward the patient are inevitably clear if we reduce them to the physician's basic responsibility in the patient-physician relationship.

And what does the physician expect of the physician in the patient-physician relationship, what does he expect of himself? If each physician had to answer this question, he would have to do so by writing his professional autobiography. Only in this way could the physician give us an adequate concept of his own ideals and ambitions, of his own expectations of himself, of his own demands upon his personal unselfishness, self-sacrifice, and capacity for whole-hearted dedication to his ideals. It is one thing to measure one's responsibilities in terms of legal obligations, another thing to measure in terms of moral obligations, quite another thing to measure them in terms of professional excellence and, finally, in terms of professional perfection. Some of us are content to walk haltingly and in stumbling fashion on the broad highroads of ethical practice, there are others who will find the harder way and who, in the desire to put first things first, will listen to counsels of perfection and to the self-imposed dictates of

one's own exacting conscience. Some of us will do the high and the right and the noble end the unselfish thing without ethics committees or without a publicly formulated code of ethics, some of us will not ask whether what we are doing is conformable to a code but whether it is conformable to ideals.

Of course, I am talking about professional competence and the progressive desire of the physician to penetrate more and more profoundly into the human being, not only through the avenues of knowledge but even more through the avenues of imaginative insight and emotional interpretation. But I am talking, also, for the development and maintenance of the physician's character in this deeply important area of human interest. No, I am not sympathetic with time studies except as broad guides. How long is the average time spent by a physician in meeting his patients in his office? How long does it take a physician on the average to see a patient in the hospital? What is the influence of a physician's patient density in the patient concentration in a hospital upon the time spent by the physician in seeing his patient? Is it worthwhile for a physician in urban or in rural practice to travel to see his patient, or must we develop other methods of effecting the contact between patient and physician?

Yes, these are important questions but even so much more important is what and who the physician is, his self-respect is important, the respect of his patients is important, the respect of society is important, but most important of all, is the fact that he carries a responsibility for which one day he will be held accountable before God.

PLANS ANNOUNCED FOR 1946 CLINICAL SURGEONS IN NEW YORK CONGRESS OF AMERICAN COLLEGES OF

The American College of Surgeons announces that arrangements have been completed for the holding of its Thirty-second Clinical Congress at the Waldorf Astoria, New York, September 9 to 13 inclusive. Plans include the usual extensive program of demonstrations, scientific sessions, panel discussions, symposia, forums, Hospital Standardization Conference, medical motion pictures, business meetings, and educational and technical exhibits, which will be held in the headquarters hotel, and operative and nonoperative clinics in the local hospitals.

This will be the first Clinical Congress since the meeting in Boston in 1941. Since that time 2,744 surgeons have been received into fellowship in absentia, and to them in particular the Convocation on

the opening night of the Congress will be a long anticipated event. Many of these new Fellows will have recently returned from service with the armed forces.

The formal initiation ceremonies, always impressive, will be exceptionally so this year because of the large number of new Fellows admitted during the past four years who are expected to be present.

Dr. Howard A. Patterson and Dr. Frank Glenn, of New York City, are chairman and secretary, respectively, of the Committee on Local Arrangements. Dr. Henry Cave of New York, a member of the Board of Regents of the College, is also active in directing the local plans for the meeting.

THE PROGRESS OF WOMEN IN MEDICINE*

ELISE S. L'ESPÉRANCE, M.D., New York City

WHEN I was asked to speak this evening for five minutes on "The Progress of Women in Medicine," it recalled to me an incident of my early college days when the professor of rhetoric said to me, "Young lady, your time is three minutes, your subject, The Immortality of the Soul." Just how can I crowd in so short a time all the vast opportunities that have been opened to medical women in the past generation?

I find that age has its compensations as it permits me to recall with great satisfaction the progress that women have made in this difficult profession during the past thirty years, and to view with pride this splendid gathering of medical men and women who are closely associated in a great profession, all looking forward equally toward the future of medicine, each willing to bear his or her part in maintaining and ever raising the standard of medical care today.

I must admit that this was not always the case. In the early days there were many limitations placed on our activities. Opportunities for medical educations were scarce. In fact, when I studied medicine there were only three standard medical colleges in the Eastern part of the United States that admitted women, they were Johns Hopkins, The Woman's Medical College of Pennsylvania, and The New York Infirmary for Women and Children. My selection was the Infirmary, which I have never regretted.

The chances for advancement after graduation in our chosen field were meager. We were a new element in a very old profession and there was a natural scepticism on the part of the medical men as to the seriousness of our intentions. This is well illustrated by an incident in my early career. In 1912, when I chose a future in pathology, one of the distinguished professors said to me that it takes twenty years to become a pathologist, and no woman would seriously consider one subject for that length of time. It may have been that remark which inspired me to remain in the field of pathology for over thirty years.

This doubtful attitude of the medical men was perfectly natural. Medicine is a serious profession and we have had to demonstrate our willingness to accept the challenge of this rigid competition. With the acceptance of this challenge, the doors of opportunity gradually began to open.

It is impossible in the short time allotted me to give you an accurate picture of the progress we have made during the past generation. It is sufficient to mention just a few important milestones.

First, medical education is coeducational in the colleges and universities in practically every large institution in the United States today, and I am proud to say that women students are maintaining a high scholastic record. Second, at present, there are very few hospitals that cannot proudly refer to their women interns and residents. Only recently, in a conversation with one of the members of the staff of a large metropolitan hospital, I mentioned the difficulty some of our women interns are having in securing residencies. He immediately replied "but we have two excellent women residents in our hospital." Third, within the past few years many women physicians have reached the high position of attendings on the staffs in some of our large hospitals and occasionally have attained the enviable status of director of a department.

These facts show the trend of the times to regard equally, without discrimination, all medical graduates.

One of the most significant achievements occurred during the past war when medical women were granted equal rank and opportunity with men in our armed services. This great advance was largely the result of the cooperation and enthusiastic support of our colleagues in the Medical Society of the State of New York who fought valiantly with us. This placed the State of New York as the first to sponsor such a step. It has also established for all time the position of women in medicine in the United States.

No great advancements are made except through a process of evolution attained through patience and perseverance. When we could demonstrate that medical women had those qualities, the acceptance of us on an equality by the medical profession was assured. Many distinguished medical women have laid the foundations for our progress in the past, the future rests with the young women of today.

The cordial feeling now existing between our two medical associations is a healthy stimulus to the success of each other. It is to this spirit of cooperation that we owe many of the successful campaigns against disease, many victories won, and many still greater to be achieved by this unity of effort.

* Delivered at the Banquet of the 140th Annual Meeting of the Medical Society of the State of New York, May 1, 1946.

PRESENTATION OF THE SOCIETY'S GOLD MEDAL TO THE OUTGOING PRESIDENT*

GEORGE W. KOSMAK, M.D., Chairman of the Board of Trustees

IT IS one of the pleasant and agreeable duties of the Chairman of the Board of Trustees of the State Society, on the occasion of its Annual Dinner, to present to the outgoing President a medal in recognition of his services to the organization during his term of office. This is a duty which I am very happy to fulfill.

Dr. Cunniffe has had a difficult path to follow since his elevation to the highest office in the gift of the Society, and he has pursued this task most efficiently and effectively. During this year, he has defended us against the imposition or attempted imposition of several measures that would have been detrimental to the progress of medicine. This has entailed great and

even unreasonable demands on his time and energy and strength. It required travel throughout the State under conditions not always too pleasant in order to bring before the doctors in various parts of the State his own views of the problems which beset the profession, coupled with exhortations which would make them realize of what an important organization they were members. Such personal contacts are of great value. In addition, he has presided over the meetings of the Council with patience and consideration. As I have said before, to properly fulfill this job is not as easy matter, and Dr. Cunniffe has acquitted himself well. We are pleased to extend to him this memento of his incumbency of the office and to wish him for the future continued health, happiness, and prosperity.

* Presented at the Banquet of the 140th Annual Meeting of the Medical Society of the State of New York May 1, 1946.

THE PATIENT DIAGNOSES THE DOCTOR

Thanks to persistent good health, I have always viewed the medical profession with calm detachment. But if I should become ill I would then be interested in your medical education, your experience and judgment, and above all, your ability to effect a quick cure—at, of course, a reasonable cost to me.

I should be alert for any neglect, delay, or supposed error on your part, since it might affect my welfare or my very existence and should expect you to give me your first and if possible, your undivided attention. As for your other patients, they and their comparatively trifling ailments would be a matter of the most profound indifference to me.

From the layman's point of view, it would seem that the smaller communities offer the doctor interested in general practice far greater opportunities for a varied and satisfying life. Small town practice places the maximum responsibility on the family doctor and gives him the maximum opportunity to know his patients and their real needs.

There is nothing in my past contacts with government bureaus which makes me enthusiastic about state medicine. I am the master who retains an expert, not a slave of a great impersonal machine.

I am much interested in prepaid insurance plans for medical, surgical, and hospital care.

The patient wants you to take him into your confidence. Barring the very sick, and the occasional unstable relative who cannot be depended upon you stand to gain by frankness. Take time to explain the patient's condition to him and to his family in simple English terms, and explain why the treatment is being ordered. This takes a few moments but it pays in every way. You are not dealing with children or imbeciles but many physicians habitually treat patients and their families as if they were.

Why do some men fossilize, others keep always in the foreground of professional progress? One man sees medicine as something static, in which all the great discoveries have been made, the other sees it as something dynamic—he eagerly awaits the proved advances. He is active in his county, state and national medical societies.

The general physician needs broader knowledge, embracing the whole field of medicine, so that he is prepared to take intelligent steps regardless of the emergency confronting him. He must have keen judgment, special ability in diagnosis, genuine interest in people, infinite patience and sympathy. In medicine the most scientific man is the one who applies the best techniques in the light of the patients' personal attributes.—J. R. Van Pelt, in *J. Missouri M.A.* Oct. 1945—*Clinical Medicine*, April, 1946.

Annual Meeting

Medical Society of the State of New York

ADDRESS OF THE PRESIDENT*

EDWARD R. CUNNIFFE, M D

I AM SPEAKING to you as the very retiring President of what may be considered the parent organization of the American Medical Association. You may recall that our state organization is forty years older than the national one and that leading members of this Society were predominantly active in the original effort to create a national organization, which now has become the largest and most important medical association in the world, far surpassing in size and extent of activities its original progenitor.

The principles of proper behavior in any walk in life, and particularly in the profession of medicine, are timeless and immutable. For forty years before the American Medical Association was formed, members of the New York State Society had adhered to certain concepts of ethics which ultimately became the "law of the land," so to speak, when formally phrased in Article 2, of the Constitution of the American Medical Association, which reads:

The objects of the Association are to promote the science and art of medicine and the betterment of public health.

And in the first section of Chapter One of its *Principles of Professional Ethics*, which reads:

A profession has for its prime object the service it can render to humanity, reward or financial gain should be a subordinate consideration. The practice of medicine is a profession. In choosing this profession, an individual assumes an obligation to conduct himself in accord with its ideals.

This language did not constitute an original promulgation at the time it was first uttered as a canon of ethics. It was merely the crystallization of the characteristics of behavior of the best medical men at all times and in all ages, embodied formally in the foregoing words.

I have presented these considerations for the purpose of making the point that it is nothing new in our tradition for emphasis to be placed on the maintenance of standards. Medicine would not have advanced through the centuries if this had not always been the motive activating the physician. For a comparatively brief period—almost a century and a half—the New York State Society has met annually for the purpose of increasing the quality of medical care, so we are indeed well fitted by a long tradition to

continue to safeguard the best interest of the public today, when pressures for social novelties have become very great.

It is interesting to compare our background and long experience in providing medical care with that of those who are so vocal in new plans to completely revolutionize the practice of medicine. It happens that the training for fitness in this pursuit resides exclusively in the medical profession and none of it inheres in the principal promoters of the schemes who can be, at best, only administrators or salesmen of the services we render. Nor are they bound by any rule of responsibility for the statements they make in espousing their cause. Ex-Mayor LaGuardia of New York City, appearing and testifying at the hearing on the Wagner-Murray-Dingell Bill in Washington, recently said that if the bill were passed, he would then stop his New York program for delivering medical care. It is extremely difficult for me to understand how he can stop anything that was never started, for this plan has never sold a policy or treated a patient. In addition, he claimed that a baby cost \$100 a pound in New York City. This, in spite of the fact that 13,459 babies were delivered in the municipal hospitals of our city during the year 1945.

That 1945 was a poor year for obstetrics in municipal hospitals can be realized, when a service delivering 200 babies per month in previous years delivered but 75 per month in 1945. I want to emphasize that for the 13,459 babies born in municipal hospitals, no doctor received any compensation, but in accordance with the time honored tradition of the medical profession, their services were freely given. This good proponent of the bill apparently did not realize that thousands of babies were delivered under the E M I C program, a program developed for the wives of men in the military forces. For these patients, the doctor's fee was \$50, except in cases where complications demanded a specialist, then the amount was \$75. The average baby weighs about six pounds. If Mr LaGuardia's charge were true, the expense would be \$600. When so many babies are delivered at such a small fee or for no fee at all, it is plain to be seen that there is something wrong with the good man's mathematics. Apparently the statement was made merely because it would attract attention by its sonorous phrasing, and advance

* Delivered at the 140th Annual Meeting of the Medical Society of the State of New York, May 1, 1946

the cause of socialized medicine, but not at all because there was any real basis to support it. Another example of this habit of overstating the truth is illustrated in the testimony of Mrs. Caroline Ware, president of the National Women's University Club, who claimed she represented 80,000 women and testified her society was in favor of the bill. Upon examination, she admitted that her society had not held a convention since before the war, and finally, she was forced to admit that she had canvassed but twenty women and the question asked was not about the bill but if they favored the extension of medical service. If they answered in the affirmative, they were supposed to favor a bill on which they had not offered an opinion. Yet she glibly reported her society in favor of it. The prize witness, however, was former Secretary Ickes who appeared in behalf of the bill and admitted that he had never read it but was in favor of it. When chided for this, he answered that most senators did not read bills before voting on them. I, myself, doubt very much whether Senators Wagner or Murray ever read the bill, and so far as Mr. Dingell is concerned, if he has read it, I am sure he does not understand it.

Mr. Altmeyer, of the Social Security Board, explained to the committee that the bill would provide medical care cheaper than the existing system because the government and the employer would help pay for it. It might be pointed out that the government gets its money from taxes only and it is a simple rule of economy that increased costs of production can only come with increased prices. Even Mr. Wallace rather belatedly admits that fact. While speaking of expense, it has been reported by some members of the Congress that for the administration of this plan it would be necessary to spend more than two billion dollars annually before a dollar goes to nurse or hospital or doctor. This expense would be for such items as directors, inspectors, paymasters, auditors, statisticians, stenographers, clerks, equipment, rent, and so forth. This figure is based on the supposition of having one inspector for every thousand patients, whereas in England experience shows there has to be one inspector for every hundred patients. Mr. Altmeyer, on questioning, was forced to admit that neither Messrs. Wagner, Murray, or Dingell wrote the bill but it was the brain child of Mr. Falk, who admits that he has spent ten years in preparing it. This is the fifth bill for socialized medicine that Mr. Falk has written and had presented to Congress by some of the New Deal representatives, the last bill being the second one he had introduced in 1945. The first four bills presented were admitted to be unsatisfactory, so, with all the government resources behind him

and an abundance of time, working for ten years, it is now shown that he has failed to succeed in this attempt. A few days after the current bill was presented, the *New York Times* published an editorial that was somewhat critical, whereupon Mr. Wagner wrote a letter to the paper stating that he knew it was not a perfect bill but hoped it would be better after the hearing.

The bill, as you know, was skillfully maneuvered away from the Appropriations Committee and into the Committee on Education and Labor, of which Mr. Murray is chairman. It would take a considerable length of time to hear all those who wanted to testify, so the chairman in his goodness and generosity decided that only those representing national organizations could appear before the committee, consequently, the New York State Medical Society, consisting of nearly 20,000 doctors who deliver medical care, is not permitted to appear but can send a statement to be placed on the record. On the other hand, the Physicians Forum, an organization which claims to have a membership about 700 and a Boston group, the remains of the old Committee of 400, were allowed to testify. These were the only physicians to testify for the bill and represent less than 2,000 members, while those doctors testifying against the bill represented 125,000. Practically all the testimony for the bill has been presented by government employees and women who represented very little. The committee, however, contains some very discerning members and it has been a daily occurrence to have the direct statements of the witnesses appearing in favor of the bill absolutely discredited upon cross-examination on their own statements.

Mr. Altmeyer, Mr. LaGuardia, and others proclaim that the doctors would make more money under this program than they receive in the present system. As a matter of fact, the definition of a profession, which is one of our principles of ethics, stresses the fact that money is not the prime object, but rather the services it can render to humanity is its goal. They say that more money will be received by the doctors and yet the program will cost the people less. It is hard to understand how pay to the physicians can be increased, plus the expense necessary to establish the enormous bureaucracy necessary to administer it and still have the cost to the people lower than at present. This will require some further explanation on the part of the proponents of the bill.

There is no substitute for experience. The experience of every country in the world that has tried compulsory health insurance has been unsatisfactory. Now they propose to give this inferior medical care to the American people, in the Wagner-Murray-Dingell Bill. It can be

likened to a hope and a wish for Utopia to arrive, coupled with an unlimited spending program to try to bring it about. It is the most unrealistic act ever proposed to the Congress, and assumes that government regulation in this country can be run more successfully than it has been in others where it has been tried. Today, the people of our country get medical care by going directly to their doctor. Under this bill a government clerk steps in between the doctor and his patient, with memoranda, schedules, rules, regulations, directives, thousands of them, changed from day to day, all instituted by the little bureaucratic gods that are appointed in droves of hundreds of thousands by the Social Security Administrator. Under this bill, the Social Security Administrator will have more power over the health of the people of the United States, vested in his own person, than could ever be assumed and exerted well by a single individual.

Let us look over the record of the countries which have accepted compulsory health insurance. Germany, which was the first country to be burdened with this program, was at one time the mecca of students from all over the globe, seeking postgraduate education. In seventy years the cost of their program multiplied one hundred times. Practically 50 per cent of all the money collected was used for overhead expenses to administer the program, the doctors receiving the benefit of practically one half. The total social taxes subtracted from the wages in Germany left the employees with little, barely enough for living expenses, and rendered it impossible for them to even leave the country and seek what offered them a more fertile field.

In England, in forty years, the cost has multiplied seventy times. A New York physician of my acquaintance who worked for a while with a London doctor reported that they had an office on one side of the house for panel patients and another on the opposite side for private patients. In a three-hour period this doctor would see 100 patients under the compulsory health insurance plan, ask them what their trouble was, give them a stock prescription, and let them depart. He never saw a single patient take off his shirt and receive an examination with a stethoscope. The secretary of the British Medical Association is responsible for the statement that no system of medical care will be successful if control of it is in the government. The failure of the system in England should be a lesson to us in this country. We see the people of England rapidly socializing everything, and preparing, perhaps, to go over in time completely to the Russian system. If that is the direction in which we are also drifting, a good way to begin is with medicine, taxing that and then moving along to the coal mines and the other industries, each new step calling for more taxes, so that the burden becomes

so great that nobody has any money left to buy anything and we all live on the largess of a beneficent and all-wise government which not only takes care of us from the cradle to the grave, but supplies us with living quarters, food to eat, clothes to wear, and rations everything out to those it likes and those it doesn't like, from shoe-strings to automobiles. I say, if that is what the American people want, the Wagner-Murray-Dingell Bill will take us a long way toward it and make each further step easier toward complete regimentation, domination, and dictatorship. This law will prepare us for such a situation by a series of headaches produced by our efforts to get a doctor when we are sick, from a government that has taken over the job of running and ruining the medical profession.

New Zealand's experience in so short a time as six years is another lesson to us, if we wish to be warned in time. According to the Minister of Health of that country, it has degenerated into a racket. He describes hospitals filled with patients with minor ailments. Doctors no longer seek improvement of their skills in postgraduate education, because they have no chance to put their abilities into practice, there is not sufficient time to spend with each patient, so extensive is the overuse of insurance facilities. Patients go to insurance doctors mainly for certificates enabling them to get paid for being sick, rather than to get over their sickness. People who are really seriously ill seldom think of using the compulsory insurance system. They go to a practitioner who does not take panel patients, and, therefore, has time to treat sick people. They would rather pay more to receive treatment from a physician who will have time to give a proper examination.

Austria and Italy have inferior medical service for their people. Dr. Dublin of the Metropolitan Life Insurance Company recently returned from a trip to Europe where he inspected the medical needs of France. He has reported that medical care delivered to the French people under compulsory insurance is very poor, and also reiterates that the medical care delivered to the people of the United States is the best in any country in the world. If such is the case, and he should be a good judge, it is hard to understand why the people of this country would listen to a proposal to establish a foreign system which has proved to be unsatisfactory.

I would like to speak on the other side of this question and tell of the great advantages that have been brought about by the medical care of the people of this country in the past seventy years under the leadership of the American Medical Association, but time will not permit. I can only say that the people of this country should consider long and carefully before they saddle such tremendous expense upon themselves and their children for inferior medical care.

House of Delegates

Minutes of the Annual Meeting

April 29 to May 1, 1946

THE 140th Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Hotel Pennsylvania, New York, New York, on Monday, April 29, 1946, at 10 20 A.M. Dr Louis H. Bauer, *Speaker* Dr F Leslie Sullivan, *Vice-Speaker*, Dr Walter P Anderton, *Secretary*, Dr W Guernsey Frey, Jr, *Assistant Secretary*

SPEAKER BAUER The House will be in order Mr Secretary, are there any disputed delegations?

SECRETARY ANDERTON There are no disputed delegations, sir

SPEAKER BAUER I declare the 140th Session of the House of Delegates of the Medical Society of the State of New York open for the transaction of business.

Section 1

Report of Reference Committee on Credentials

SPEAKER BAUER The Chair recognizes the Chairman of the Credentials Committee, Dr McCarty

DR. CHARLES F MCCARTY, Kings At the last count there were eighty-four County Delegates, fifteen Officers, one District Delegate five Section Delegates and one Ex President registered.

SPEAKER BAUER Is there a quorum present?

SECRETARY ANDERTON There is a quorum present, sir

SPEAKER BAUER There being a quorum present, we will proceed with the order of business.

Section 2

Approval of the Minutes of the 1945 Session

SPEAKER BAUER The first order of business is the approval of the minutes of the 1945 Session

SECRETARY ANDERTON Mr Speaker, I move that the reading of the minutes be dispensed with, and that they be approved as published in the December 1 and December 15 1945, and the January 1 and January 15, 1946 issues of the NEW YORK STATE JOURNAL OF MEDICINE.

DR. EIRA A. WOLFF, Queens I second the motion.

There being no discussion, the motion was put to a vote and was unanimously carried.

Section 3

Reference Committees

SPEAKER BAUER Mr Secretary, will you read the appointments of the Reference Committees? Gentlemen, will you please pay close attention, because there are several changes from the printed list which appeared in the JOURNAL.

SECRETARY ANDERTON The Reference Committees for the 1946 House of Delegates are as follows

REFERENCE COMMITTEE ON CREDENTIALS:

Charles F. McCarty, *Chairman* Kings County
Goodwin A. Dwyer, *Queens County*
Felix Ottaviano, *Madison County*
Alexander N. Selman, *Rockland County*
E. Kenneth Horton, *Nassau County*

REFERENCE COMMITTEE ON REPORT OF PRESIDENT

Eira A. Wolff, *Chairman* Queens County
John A. Pritchard, *St Lawrence County*
Raymond F. Kircher, *Albany County*
Thurman B. Olvan, *Kings County*
Ralph Sheldon, *Wayne County*

REFERENCE COMMITTEE ON REPORTS OF SECRETARY CENSORS AND DISTRICT BRANCHES

Morris Mason, *Chairman* Warren County
Robert C. Simpson, *Montgomery County*
Frank Telford, *Richmond County*
Charles H. Loughran, *Kings County*
J. Lewis Amster, *Bronx County*

REFERENCE COMMITTEE ON REPORTS OF TREASURER, TRUSTEES AND FINANCE COMMITTEE

Fenwick Beekman, *Chairman* New York County
Morris Ant, *Kings County*
Benjamin Abramowitz, *Sullivan County*
Roger A. Hemphill, *Livingston County*
Bradford P. Golly, *Oneida County*

REFERENCE COMMITTEE ON REPORT OF PLANNING COMMITTEE FOR MEDICAL POLICIES

Albert F. R. Anderson, *Chairman* Kings County
W. Walter Street, *Onondaga County*
Edward C. Veprovsky, *Queens County*
Harry C. Quam, *Erie County*
John R. MacElroy, *Saratoga County*

REFERENCE COMMITTEE ON CONSTITUTION AND BYLAWS AMENDMENTS

Peter J. Di Natale, *Chairman* Genesee County
Clifford F. Lee, *Chemung County*
Joseph C. O'Connor, *Erie County*
Donald E. McKenna, *Kings County*
Francis G. Riley, *Queens County*

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART I:

Postgraduate Education (also Supplementary)
Joseph Tanoppy, *Chairman* Kings County
Vincent Juster, *Queens County*
Joseph H. Diamond, *Richmond County*
George C. Vogt, *Broome County*
Stockton Kimball (Section Delegate)

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART II:

Maternal and Child Welfare (also Supplementary)
Joseph A. Oels, *Chairman* Essex County
Alfred K. Bates, *Cayuga County*
Blahon C. Halleck, *Otsego County*
William J. Orr (Section Delegate)
Alfred M. Hellman, *New York County*

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART III:

School and Industrial Health
David W. Beard, *Chairman* Schoharie County
John C. Brady, *Erie County*
Irving S. Banda, *Kings County*
William J. Tracy, *Schenectady County*
Samuel M. Kaufman, *New York County*

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART IV:

Public Health Activities
Blood and Plasma Exchange Bank
Cancer (also Supplementary)
Hard of Hearing and the Deaf
4 H Clubs and Youth Health Activities
Frank La. Catutta, *Chairman* Bronx County
Jacob Warner, *Queens County*
Donald Malvern, *Dutchess County*
Arthur M. Johnson (Section Delegate)
Edgar O. Boggs, *Lewis County*

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART V

Rehabilitation
Rural Medical Service
Kenneth F. Bott, *Chairman*, Greene County
Charles S. Lakeman, Monroe County
Robert B. Archibald, Westchester County
Madge C. L. McGuinness, New York County
Theodore W. Neumann, Orange County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART VI

Public Relations and Economics
Public Medical Care
Women Medical Students and Interns
Medical Service and Public Relations
Roy B. Henline, *Chairman*, New York County
John M. Galbraith, Nassau County
Lyman C. Lewis, Allegany County
Archibald K. Benedict, Chenango County
Elton R. Dickson, Broome County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART VII

Medical Care Insurance
Special Committee on National Casualty and Indemnity Insurance
Herbert E. Wells, *Chairman*, Erie County
Benjamin M. Bernstein, Kings County
Joseph D. Hallinan, Queens County
Oswald J. McKendree, Oneida County
Clarence G. Bandler, New York County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART VIII

Veterans' Affairs
Joseph P. Henry, *Chairman*, Monroe County
John P. O'Brien, Bronx County
Leo E. Gibson, Onondaga County
Edwin A. Griffin, Kings County
Reginald A. Higgons, Westchester County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART IX

Legislation (also Supplementary)
Frederic W. Holcomb, *Chairman*, Ulster County
Thomas B. Wood, Kings County
Sylvester C. Clemons, Fulton County
Andrew A. Eggston, Westchester County
B. Wallace Hamilton, New York County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART X

Workmen's Compensation
William B. Rawls, *Chairman*, New York County
Bernard S. Strait, Yates County
Stanley E. Alderson, Albany County
Renato J. Azzari, Bronx County
G. Kirby Collier, Monroe County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART XI

Publications and Medical Publicity
George C. Adle, *Chairman*, Westchester County
Stephen H. Curtis, (District Delegate)
Louis A. Friedman, Bronx County
Scott Lord Smith, (District Delegate)
Charles C. Trembley, Franklin County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART XII

Malpractice Defense and Insurance
Report of Legal Counsel
Eugene H. Coon, *Chairman*, Nassau County
Donald D. Prentice, Albany County
Joseph A. Landy, Bronx County
Gny S. Philbrick, Niagara County
John L. Sengstack, Suffolk County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART XIII

Miscellaneous Matters
Convention
Medical Licensure
Nursing
Woman's Auxiliary
Office Administration and Policies
Joseph H. Cornell, *Chairman*, Schenectady County
Charles A. Prudhon, Jefferson County
Abraham Koplowitz, Kings County
Philip D. Allen, New York County
Richard P. Doody, Rensselaer County

REFERENCE COMMITTEE ON NEW BUSINESS A

Thomas M. D'Angelo, *Chairman*, Queens County
Leo F. Schuff, Clinton County
John J. Ganev, Kings County
Harold B. Davidson, New York County
James E. McAskill, (Section Delegate)

REFERENCE COMMITTEE ON NEW BUSINESS B

Leo F. Simpson, *Chairman*, Monroe County
Edgar Bieber, Chautauqua County
Arthur A. Fischl, Queens County
John Dugan, Orleans County
A. Wilbur Durfee, New York County

REFERENCE COMMITTEE ON NEW BUSINESS C

Frederick W. Williams, *Chairman*, Bronx County
Charles A. Anderson, Kings County
Denver M. Vickers, Washington County
John L. Edwards, Columbia County
Theodore J. Curphey, Nassau County

SPEAKER BAUER Thank you, Mr. Secretary (Announcements concerning time and place of meeting of various Reference Committees)

SECRETARY ANDERTON I move that the reports and supplementary reports of Officers, Council, Trustees, Legal Counsel, and District Branches, that have been published and distributed to the members of the House, be referred to the respective reference committees without reading.

DR. GEORGE W. KOSMAK I second the motion.
SPEAKER BAUER You have heard the motion. Most of the reports were sent to you in printed form prior to the meeting. There are several reports that have been distributed to you this morning. Is there any objection to their being referred without reading? If not, they will be so referred, but take notice of the following. All of the printed reports are referred to the respective Reference Committees with the exception of one portion of the Report on Malpractice Defense and Insurance pertaining to amendments of the Bylaws, which is referred to the Committee on Amendments to the Bylaws, otherwise, the report is referred to Reference Committee on Report of Council, Part XII. Also, the report on the Finance Committee is referred to the Reference Committee on the Reports of the Treasurer and Trustees. Otherwise, the supplementary reports are referred to the respective committees as noted in the titles.

Section 4 (See 57)

Supplementary Report of Secretary

To the House of Delegates—Gentlemen,

It gives your Secretary pleasure to draw your attention to a matter which has developed since presenting his Annual Report.

Owing to an increase in the incidence of diphtheria in several localities in this State, your Secretary attended, on April 17, 1946, with Mr. Dwight Anderson, Executive Secretary of the Medical Society of the State of New York, a meeting organized by Dr. Donald Armstrong, Vice-President of the Metropolitan Life Insurance Company, at his offices. Also present were other representatives of the Metropolitan Life Insurance Company, the New York State Health Department, and the State Charities Aid Association.

A program was discussed, aiming toward increasing the number being immunized against diphtheria and in increasing the immunity of those previously immunized against diphtheria in New York State.

Your Secretary petitions the House of Delegates to direct the Treasurer of the Medical Society of the State of New York to pay Dr. J. Stanley Kenney \$153.23 for his expenses incurred as delegate to the American Medical Association House of Delegates,

also \$77.27 for his expenses, while attending the House of Delegates meeting at Buffalo, New York, making a total of \$230.50. As Dr. Kenney's voucher was submitted more than ninety days after he had incurred these expenses the Council and the Board of Trustees have not the power to direct payment (Chapter X, Section 1, Bylaws of the Medical Society of the State of New York.)

Respectfully submitted,

W. P. ANDERSON, M.D., Secretary

April, 1946

Section 5 (See 48)

Supplementary Report of the Council—Part I Postgraduate Education

To the House of Delegates—Gentlemen,

As Chairman of the Council Committee on Public Health and Education, I herewith submit a supplementary report to include the activities of the Committee since March 13, 1946.

Postgraduate Education

In addition to the instruction mentioned in the report of the Council Committee on Public Health and Education submitted on March 5, 1946, instruction has been arranged for and given in the following county medical societies:

| County | Instruction | Number of Lectures |
|--------------|---------------------------------|--------------------|
| Broome | General medicine | 1 |
| Jefferson | General medicine | 2 |
| Oneida | General medicine | 1 |
| St. Lawrence | General medicine | 1 |
| Schoenectady | Chemotherapy and the antibiotic | 1 |
| Seneca | General medicine | 1 |
| Steuben | General medicine | 1 |
| Tompkins | General medicine | 1 |
| Ulster | Tropical diseases | 1 |
| Warren | Traumatic surgery | 1 |
| Wyoming | Cancer | 1 |

Since the meeting of the House of Delegates in Buffalo in October 1945, the Committee has arranged for postgraduate instruction to be presented in thirty-one counties with a total of ninety-eight lectures.

At the request of the Convention Committee, the Council Committee on Public Health and Education has arranged for a Teaching Day especially for the members of the Medical Society of the State of New York who served their country during World War II, to be held at the time of the Annual Meeting on Tuesday, April 30, 1946, Hotel Pennsylvania, New York City. This Teaching Day will consist of eight lectures—four lectures will be given in the morning and four lectures will be given in the afternoon. Subjects were selected which will not conflict with the Scientific Section and Session programs, to be held Wednesday, Thursday, and Friday.

Section 6 (See 47)

Supplementary Report of the Council—Part II

Maternal and Child Welfare

Child Welfare—A nation-wide child health survey is being conducted by the American Academy of Pediatrics, the Children's Bureau of the United States Department of Labor, and the United States Public Health Service. An outline of the plan was submitted to the Subcommittee on Child Welfare. It was decided to recommend to the Council approval of the plan and request the Medical Society of the State of New York to assist in the study. These suggestions were approved by the Council of the Medical Society of the State of New York at the meeting on March 14, 1946. Since that time,

several conferences have been held with representatives of the agencies conducting the survey and the Medical Society of the State of New York has already given considerable assistance.

A meeting of the Subcommittee on Child Welfare was held in New York City on Thursday, April 11, 1946 to consider a program for "Pediatric Institutes for General Practitioners." The Subcommittee approved the program as did the Council Committee on Public Health and Education. The necessary arrangements are now being made to hold these Institutes in various parts of the State under the joint auspices of the Medical Society of the State of New York and the New York State Department of Health.

Section 7 (See 53)

Supplementary Report of the Council—Part IV

Public Health Activities

Cancer—At the time of the meeting of the Subcommittee on Cancer and the Council Committee on Public Health and Education on March 13, 1946, a request was made to Dr. Louis C. Kross, Chairman of the Board of Directors of the New York State Unit of the American Cancer Society, to submit a plan of reorganization and operation to be developed in New York State. This has been received and will be considered at a meeting of the Subcommittee on Cancer and the Council Committee on Public Health and Education to be held in New York City on Sunday, April 28, 1946.

4-H Clubs and Youth Health Activities—Dr. J. G. Fred Hiss, Chairman, Subcommittee on 4-H Clubs and Youth Health Activities, reports his correspondence with Mr. B. R. Rickards, Director, Division of Public Health Education, New York State Department of Health and with Mr. Albert Hoefler, State 4-H Club Leader. Dr. Hiss has been active for several years to change the plan for judging the health of boys and girls in 4-H Clubs. The suggestions made by Dr. Hiss were accepted by the New York State group of 4-H Clubs and, recently at a meeting of the leaders at the National 4-H Club Congress, the following action was taken as reported by Mr. Hoefler:

"At that time I did raise the question and you and your colleagues will be interested to know that the Subcommittee has recommended discontinuance of the health screenings as have been conducted in the past and recommended the New York State plan. For 1946 we are recommending that the health screenings be made on the basis of improvement based on the Standard Report form and some additional information and that a blue award group be selected based on health improvement from the records submitted. Health records will be submitted at the same time and all other records are due and will be scored by the committee. States will be permitted to submit records of one boy and one girl."

Section 8 (See 78)

Supplementary Report of the Council—Part V Rehabilitation

A meeting of the Subcommittee on Rehabilitation and the Council Committee on Public Health and Education was held in New York City on April 9, 1946. Also present at this meeting were officers of the Medical Society of the State of New York, representatives of the New York State Departments of Education and Social Welfare and Dr. Victor H. Vogel, Chief Medical Officer for the Federal Office of Vocational Rehabilitation. Because of illness, the

New York State Department of Health was not represented

The usual discussions regarding the fee schedules took place. Comment was made by Dr. Vogel and others that there should be additional activities carried on under the Office of Vocational Rehabilitation of the New York State Education Department. Provision for physical examination of all applicants for rehabilitation is required. It was agreed that a fee for this examination would be submitted and that a physician devoting his time to internal medicine would be recommended to the Council for appointment to the Subcommittee on Rehabilitation.

It was also agreed that a fee schedule should be submitted for psychiatric patients who are now applying for care under the Rehabilitation program. This report was made to the Council at its meeting on April 11, 1946.

Dr. Albert F. R. Andresen, Brooklyn, was appointed a member of the Rehabilitation Subcommittee.

Provision for the psychiatric part of the program is being developed.

Section 9 (See 56)

Supplementary Report of the Council—Part IX.

To the House of Delegates—Gentlemen,

The Council Committee on Legislation respectfully submits a supplementary report.

The preliminary report was made on March 1. As the legislative session lasted through March 26, the total number of bills introduced in both houses and those in which we were interested could not be reported at that time, also, we could not give you the final action on many of the bills in which we were interested. There were 2,437 bills introduced in the Senate and 2,774 bills introduced in the Assembly, a total of 5,211 in both houses. Your Legislative Committee followed 136 bills in the Senate and 166 bills in the Assembly, or 302 bills in all. Of these bills, 122 were concurrent, leaving 280 separate bills.

At the time of the preliminary report, we could give you final action on very few of these bills. In that report we mentioned that the antivivisection bills had been defeated in the committee in the Senate, but remained in the Judiciary Committee in the Assembly. The final action was defeat in committee in the Assembly on both antivivisection bills. We also reported to you that a bill for the licensure of chiropractic had been introduced in the Assembly on February 27. No bill for the licensure of chiropractic was introduced in the Senate and this bill in the Assembly was defeated in committee.

In the earlier report we also called your attention to the very large number of compensation bills that had been introduced this year. At this time we can report to you that a very high percentage of these bills were either not reported out of committee or were defeated in committee. The fate of those that were passed by both houses has not been good in the hands of the Governor. In other words, there seems to have been a general attitude throughout the Legislature this year, not to make any marked changes in the Compensation Law this year. The Society was interested in sponsoring at least one-half dozen bills pertaining to workmen's compensation and these bills suffered the same fate as the great majority of the other workmen's compensation bills. Senate Int 612—Condon, which amended the Workmen's Compensation Law and, among other changes, struck out provision for committee of ex-

pert consultants, passed both houses but was vetoed by the Governor. We were on record as not being in favor of this bill and were pleased with the action of the Governor.

A bill was introduced on Thursday, March 14, Assembly Int 2739—Rules Committee, to authorize the State Tax Department to receive Federal moneys for construction of public and other non-profit hospitals, including health centers, postwar public works planning commission or other agency designated by Governor shall be sole agency for administration if Federal law requires that State agency be designated. This bill provides for the State to administer Federal funds under the Hill-Burton, or a similar bill, if such Federal legislation is passed. Your Legislative Committee went on record as being in favor of this bill, which was passed by both houses, signed by the Governor and becomes Chapter 666 of the Laws of 1946.

The Legislative Committee, on the advice received from the Advisory Committee on Ophthalmology, went on record as being opposed to the bill, Senate Int 1563—Wicks, which provided for the practice of ophthalmic dispensing. The opposition was based on the provision in this bill permitting the fitting of contact lens by optometrists. The disapproval of that provision in the bill was made known to the committees in the Legislature and on March 15 the bill was amended, removing that provision. Your Legislative Committee, after further consultation with the Advisory Committee on Ophthalmology, went on record with the committees of both houses that they were then in favor of the bill as amended on March 15. The amended bill passed both houses and was signed by the Governor and now is known as Chapter 697 of the Laws of 1946.

Your Legislative Committee went on record as being opposed to the bill, Senate Int 1695—Condon, which changed the definition of the practice of podiatry. It was thought that the new definition did not contain the limitations to the practice of podiatry that are now in the present definition and the removal of these limitations would be a danger to the public. Responses from many members of the State Society and members of the Legislative Committees of the County Societies in registering their opposition to this bill apparently were effective, as the bill which had passed both houses was vetoed by the Governor.

The bill, Senate Int 1319—Griffith, which amends the present law governing the selling and prescribing of barbiturates and other hypnotic and somnifacient drugs, was passed by both houses and signed by the Governor and becomes Chapter 597 of the Laws of 1946. The Society was on record as being in favor of this bill.

At the time of writing this report, there are still a few bills remaining in the hands of the Governor on which he has not acted. Among these bills is Assembly Int 802—Ryan, which amends the present Narcotic Law in regard to manufacture and sale of narcotic drugs, preparations, and defines exempt narcotic preparations. It is understood that this bill has an excellent chance of being signed by the Governor, but at the time of writing this report, this action has not been taken and we cannot give you the final action by the Governor or the chapter number. There is, also, the bill, Senate Int 1651—Griffith, which transfers from the Education Department to the Health Department jurisdiction of the care and treatment of physically handicapped children. Again, this bill has not been signed by the Governor at the present date and we cannot give you the final action.

The bill, Assembly Int 2274—Maffior which is known as the "tuberculosis bill," provides for care and treatment by state, county, or city, of persons suffering from tuberculosis without cost unless the person volunteers to pay, and which provides that localities may retain their institutions or transfer them to the State, and, also, that the State will pay about 60 per cent of expenses on patient-day basis, passed both houses and is in the hands of the Governor. To the present date the Governor has not signed this bill, but we understand that there is little likelihood of its being vetoed. We regret at this time that we cannot give you the final action or chapter number.

To sum up the report of the Council Committee on Legislation for this year it can be said that your Committee has been very busy following a large number of bills, has registered its recommendations on those bills with the committees in both houses and with the Governor. The results of this legislative session would appear to be highly satisfactory. It is regretted that some of the workmen's compensation bills in which we were interested were not acted on favorably but it is realized that their fate was no different than the great majority of the workmen's compensation bills that were introduced this year. The action taken by members of the Legislature in both houses and by the Governor has been to a very large extent along the lines which your Legislative Committee has desired.

Respectfully submitted,
HARRY ARANOW, M.D., Chairman,
Council Committee on Legislation

Section 10 (See 55)

Additional Annual Report—Report of the Finance Committee

To the House of Delegates—Gentlemen,

The House of Delegates at its last session adopted the following resolutions

Resolved, that the House of Delegates of the Medical Society of the State of New York requests the Board of Trustees to establish a fund for the advanced education of the children of our colleagues who have died in the service of our country, and be it further

Resolved, that said fund may be raised by a small increase in dues or annual levy over a period of years, for example, one dollar per year for ten years, in order that each member may have a part in the memorial."

The Council referred this to the Finance Committee for study

The Finance Committee found itself unable to make any concrete recommendations without knowing more about the scope of the problem

The Committee sent a questionnaire to each county society requesting information as to the number of doctors who had died in service and the names, ages and sex of any children. So far, replies have been received from 54 of the 61 county societies.

From the counties reported, there are a total of 54 children who would be effected by the resolution. Twenty nine are boys, and 25 are girls. Their age groups are as follows

| Age | Number | Boys | Girls |
|-----------|--------|------|-------|
| 0-5 years | 19 | 13 | 6 |
| 6-10 | 19 | 10 | 9 |
| 11-15 | 9 | 3 | 6 |
| 16-20 | 5 | 2 | 3 |
| Over 21 | 2 | 1 | 1 |
| Total | 54 | 29 | 25 |

Of the seven counties not reporting, only one will materially affect these figures. That county is New York, and it may be expected that as a rough estimate we may have 20 children and possibly more from that county to provide for. No definite estimate, of course, can be given until all counties have reported.

It will be seen from the above listings that there will be only a few children who are in the advanced education stage and, therefore the peak load will not come for several years.

Before the Committee can proceed any further even after all questionnaires have been returned, it will be necessary for the House to clarify the resolution.

First, what is meant by "advanced education"? Does it mean college, professional school, or both? The Finance Committee recommends that the plan be restricted to college education for all and, in addition, professional education only for those who wish to study medicine. The House should also place a limit on the number of years of education to be provided.

Second, should financial need be a determining factor? The Finance Committee recommends that this education be provided only for those who otherwise would not be able to obtain it.

Third, how extensive provision for financial help does the House wish to make? Should there be a straight scholarship of a fixed sum, or should the amount cover tuition and other obligatory fees, or should it cover the latter plus a fixed allowance for board and room?

Fourth, the final paragraph of the Resolution does not confer the authority on either the Council or Trustees to raise the annual dues as its content is too indefinite.

With reference to this the Finance Committee recommends that voluntary contributions be asked for, during the next five years. Each county society may be requested to add a plea on their annual bills for voluntary contributions to the War Memorial. It is believed that sufficient money can be raised this way without any increase in dues or compulsory assessment. If not, the balance should come from the general funds of the Society.

The Committee also recommends that the plan be limited to sons and daughters of deceased veterans and not to include grandchildren.

Finally, the Committee recommends that authority be conferred by the House on the Council to determine the method of administration of the Program and to make appropriate recommendations regarding the financial aspects to the Board of Trustees.

Respectfully submitted,
LOUIS H. BAUER, M.D., Chairman
J. STANLEY KENNEY, M.D.
F. LESLIE SULLIVAN, M.D.

- A New York State Plan for Survey of Hospital Facilities and Program for Regional Hospital Planning for Postwar Hospital Construction
- B Principles for Group Practice Approved by the Coordinating Council of the Five County Medical Societies of Greater New York, November 1, 1945
- C National Health Program of the American Medical Association, adopted February 23, 1946, by the Board of Trustees of the American Medical Association

To the House of Delegates—Gentlemen,

Organization—The Planning Committee for Medical Policies was continued by the House of Delegates at its Annual Meeting in 1945, and its organization was on the same basis as in the previous two years. Its personnel therefore was as follows:

J Stanley Kenney, M D, *Chairman*, New York
 Edward R. Cunniffe, M D, Bronx
 William Hale, M D, Utica
 W P Anderton, M D, New York
 A. A. Gartner, M D, Buffalo
 Louis H. Bauer, M D, Hempstead
 Peter J. Di Natale, M D, Batavia
 Norman S. Moore, M D, Ithaca
 Walter S. Mott, M D, White Plains
 O W H Mitchell, M D, Syracuse
 Leo F. Simpson, M D, Rochester

The period covered by this report is from October 8, 1945, to April 10, 1946. This represents a period of six months since the rendering of your Committee's last annual report, which was a very comprehensive survey and covered a wide range of topics. For this short year it seemed wise and consistent with the trends for your Committee to confine its studies to what it considered the more important problems requiring clarification. It elected, therefore, to concentrate its efforts on two major programs—Diagnostic Aids and Health Centers, and Group Medical Practices. In addition, it has studied the National Health Program and again reviewed the current Wagner-Murray-Dingell Bills, and has commented briefly on a few of the other subjects which were carefully considered in its 1945 report.

Interim Report—We are rendering this as an interim report. Both of the above-mentioned subjects represent continuing programs and our study of them, therefore, is necessarily incomplete. Because of the inherent complexity of these two problems we found ourselves confronted with obstacles which precluded any hasty or ill-considered recommendations, and much more time for their solution will be required.

Diagnostic Aids and Health Centers—The Council of the Medical Society of the State of New York on November 8, 1945, voted that the following recommendation be referred back to the Planning Committee with the request for more detailed information as soon as possible:

Centers for Diagnostic Aids

The Planning Committee recommends as an experiment that a Center for Diagnostic Aids to physicians practicing in the rural districts be set up in a selected location in either or both of the following designated areas:

- (1) The counties of Schuyler, Chenango, and Tioga
- (2) The north and northeastern part of Delaware County, the southwestern part of Otsego County, and the southeastern part of Schoharie County

This specific recommendation from the Council has formed the basis for this study.

For purposes of clarification it would seem advisable to restate what is meant by "centers for diagnostic aids." The Hill-Burton Bill defines a public health center as a "publicly owned facility for the provision of public health services and medical care, including related facilities such as laboratories, clinics, and administrative offices operated in connection with public health centers."

That portion of the Planning Committee report of 1945 which related to diagnostic centers reads as follows: "The term 'laboratory facilities' means in addition to routine chemical, bacteriologic, and serologic examinations and other pathologic work, the related clinical tests such as x-ray examinations, electrocardiograms, basal metabolism tests, and similar clinical procedures. Blood transfusions also should be made available, but this facility is being provided by a particular setup now developed as the result of legislative action at the 1945 annual session."

"The primary purpose of these centers is not to furnish a diagnosis, but rather to make available to the physician in attendance the results of all such tests, thereby enabling him to make his own diagnosis. No treatment is to be provided. No member of the staff of such a center is to be permitted to engage in the private practice of medicine."

A subcommittee of this Planning Committee, consisting of Dr. O W H Mitchell and your chairman, together with Dr. Leslie Sullivan and Dr. Robert Hannon, held a meeting in Albany which was attended by Dr. Godfrey, State Commissioner of Health, Dr. Rogers, Deputy Health Commissioner, Mr. Harry Page, representing Mr. Lonsdale, Commissioner of Public Welfare, Dr. Berkel of the Welfare Department, and Dr. Bourke representing Assemblyman Lee B. Mailer, Chairman of the Health Preparedness Commission, who was unable to attend himself, because of the necessity of being present at the legislative sessions. Dr. Bourke is the director of the study for the Joint Hospital Board of the New York State Postwar Public Works Planning Commission.

Dr. Bourke gave us a general survey of the planning the State is undertaking through this Joint Hospital Board and he furnished us with a copy of their preliminary report dated February 15, 1946, and known as "New York State Plan for Survey of Hospital Facilities and Program for Regional Hospital Planning for Postwar Hospital Construction" (See Appendix A).

These gentlemen evinced great interest in the survey made in 1945 by the subcommittee on Laboratory Services and Medical Care of which Dr. F. Leslie Sullivan was chairman. We reminded them that the State Society is deeply interested and concerned with methods to provide quality medical care in rural and outlying districts and in order to attract doctors to practice in these areas and to furnish them with the facilities to do so. The diagnostic aid center would be a means to this end. How to finance and administer such centers and insure efficient control of them by the doctors remains the crux of the problem.

They discussed in a general way the program of state aid for public health work, but believe that such plan or plans as may be evolved should be integrated with the program for regional hospital planning and postwar hospital construction which New York State contemplates. They anticipate having the local community, with state aid where necessary, maintain its own hospital facilities as far as possible, but again they retained the basic con-

ception of having these facilities tie up with the regional general hospital and medical center. They felt, therefore, that the diagnostic clinic or public health center—or whatever designation it ultimately will be given—should be an intrinsic part of the basic plan. Either such a center could be incorporated in an existing hospital or, where new ones are built, provision could be made for such centers in these hospitals. Dr. Bourke appeared sympathetic to the State Society's idea of a local experiment of setting up a diagnostic center in such a section as the Delaware-Scholastic area.

Much confusion still exists as to what a health center should be. The broader concept of it assumes such a facility to be prepared to house and furnish all technical services. This would include specialist and consultant services. Dr. Godfrey could not visualize these health centers without adequate provision for consultation service which would, of course, mean services of specialists. They stressed, also, the possible political and legal difficulties which would have to be overcome, and believed that great pains would have to be exercised to secure the full consent and cooperation of all local boards and local officials in the interested areas.

Your subcommittee brought out emphatically that whatever plans are being considered for any locality, we must know, first, what the professional groups think about it, second, what the local sentiment is toward such a "center", third, specific details of any facilities contemplated or needed, fourth, how to finance these schemes, fifth, that such centers at all times have competent professional guidance.

It was the consensus of everyone that more exploratory work would be necessary. Furthermore, it was not clear to these officials how the State could assist. The discussion also brought out the fact that there were many other difficulties to be met, especially in the municipalities which operate under their own laws.

The organization of district councils to work with local agencies to cope more promptly with important or urgent matters which might arise was suggested. Such councils, it was felt, might serve a purpose similar to that of the Coordinating Council of the Five County Medical Societies of Greater New York, and thus protect medicine's rights and interests. These councils would clear through some kind of central planning committee which, again, could be integrated into the general regional planning program.

Much, if not all, of the State planning appears to depend on the enactment into law by Congress of the Hill-Burton Bill S-191. At the time of the writing of this report (April, 1946) the status of this legislation is most dubious. While it has already passed the Senate, and though the House Committee has held hearings upon it, its passage by the House is by no means certain.

There was no provision in the bill which passed the Senate for financing the operation or maintenance of the hospital. Assuming that this bill fails of enactment, it would seem probable that the State planning would have to be revised, and necessarily would fall back on State aid programs adopted many years ago of appropriating monies for the development of hospitals and related facilities. Such appropriations would have to be granted by the State Legislature.

We expressed the hope that the Medical Society of the State of New York might be able to implement a diagnostic center as an experiment in one of the areas needing such diagnostic aid, with the State assisting, perhaps, in a financial way. It was sug-

gested that this might be done under the provisions of an old existing law.

The comprehensive report of the Committee on Rural Medical Service of the American Medical Association has been reprinted in full and appears in the minutes of the December 12, 1945, meeting of the Planning Committee. It is too long to incorporate in this report. It presents a detailed survey of the medical and health problems involved in the rural areas throughout the various states. It discusses problems which are comparable to those existing in many of our upstate rural communities and should be of considerable assistance in guiding our thinking and planning.

Regional conferences under the auspices of the Joint Hospital Board of the New York State Post-war Public Works Planning Commission have already started. The first one has been held recently in the Albany area and the second one for the New York area is scheduled at an early date. To these meetings have been invited representatives of the New York State Hospital Association and its local councils, trustees and superintendents of hospitals in the region, representatives of the medical and nursing professions, the deans of the medical schools and representatives of public health and social welfare, agriculture, labor, and industry. A 22-page inventory is being circulated among hospitals in the area which is to be filled out and returned as early as possible. After all these reports have been received, they will then start their planning. They ask particularly at this time that no region start either to expand its hospitals or build new hospitals or anything of that nature. While this organization and planning is contingent upon the passage of the Hill-Burton Bill, nevertheless, if it fails of enactment, it is probable that bills will be introduced into the next legislature to implement their program on State funds if Federal funds are not available.

The foregoing résumé will serve to inform you, at least superficially, of the difficulties encountered where State Society thinking and planning within the framework of our present medical practice clashes with the ideas and plans of health and related government authorities. Both seek the same objectives. How to achieve these objectives and correlate conflicting ideologies is a dilemma. The State Society desires competent professional guidance for such centers and control retained by the doctors. The administration and financing of these centers, based on this principle, with at least partial State aid and cooperation, poses our most vexing problem.

The State Society is anxious to assist in the working out of plans for the improved medical care contemplated for rural communities. The whole subject of centers for diagnostic aid will entail conferences with local professional and lay agencies in the communities concerned and further contacts with state officials and it may have to await the outcome of both the State's survey of hospital facilities and of the pending legislation. Your Committee proposes to hold such conferences, particularly with representatives from the areas recommended for experiment in the Sullivan Committee report. We cannot move in the development of any plan with preciseness or sureness until all these facts have been ascertained.

It was the sense of the Committee after considered deliberation to make no recommendations on this subject at this time, rather to bring before the House for their information these points brought out in our discussions, what the difficulties have been and why the directive to establish one or two experimental centers has not been put into effect.

Group Medical Practice—Your Planning Committee in its annual report in October, 1945, made general reference to the problem of group practice. Since that time, interest in this phase of medical practice continues to mount. This method of practice forms an integral part of at least one contemplated medical prepayment insurance plan in metropolitan New York. It intrigues other medical groups, including our large medical schools and teaching centers. Young physicians are now coming out of the military services in increasing numbers, and some are finding it difficult to enter private practice for the first time and others to renew their former practices. Many of these men are profoundly interested in group practice.

A special subcommittee of the Planning Committee under the chairmanship of Dr. Di Natale, has given considerable study to the over-all problem of group practice. There has been marked advance in the character of the practice of medicine in the past twenty-five years, and what originally started as a trend toward cooperative effort in rendering medical care has now become a major feature and probably will become increasingly so within the next few years. The impetus given public opinion along this line by developments coming out of the war effort has made it imperative for the medical profession to develop new methods of distributing medical care.

Experience in the past where group practice has succeeded has shown that in any group one member has been in absolute control and has demonstrated the ability to assemble a competent group around him which has submitted to his authority. Furthermore, such groups have maintained the highest standards of medical ethics. The principle must be definitely accepted, namely, that the ethics of a group must be the same as the ethics of an individual in the practice of medicine. That is one thing that must be insisted upon, because the relationship of a group to other practitioners is very important.

The advocates of group practice point out that it furnishes the answer to many of the personal problems of everyday working conditions, time for rest and relaxation, vacations, periods of study and investigation, and time for postgraduate work, social and financial safeguards, it prevents duplication of overhead and provides the public with more adequate medical care by having a doctor available at all times and having readily available consultation services.

It is true that a patient very frequently will get more laboratory procedures and more consultations than may be needed. Fifteen per cent would seem to be an ample estimate of those patients seen daily who require the broader and more specialized laboratory and diagnostic procedures. Medicine practiced in many groups is inferior to medicine practiced by many men outside of groups. Many groups have broken up because of the petty jealousies created where perhaps one man brought in more income than another member of the group. A physician must be built for group practice. There may be a tendency to exploit younger physicians and some feel that there is loss of individuality when one is part of a group.

Group practice must be a partnership in the sense that everyone who joins the effort must be willing to subordinate his own personal desires to the work of the group as a whole.

Group practice tends to make for impersonal medicine. This is the very thing that the American people have been sensitized against. We stress the doctor-patient relationship. Some one person in the group, usually the internist, must be designated to

be the one responsible for the assembling of all data and transmitting these findings to the patient. In other words, the patient must have his own doctor in the group.

There are many questions that involve the combination of independent group practice and group payment. Recognition within the group must be given to such matters as adequate income for each member and reasonable stable tenure as a member of the group. The method of compensation must be carefully worked out. These represent only a few of the administrative problems that must be met.

The Coordinating Council of the Five County Medical Societies of Greater New York recently has set up a set of principles for group practice. These principles are incorporated in this report as *Appendix B*. They constitute a reasonably sound framework which should guide the organization of any group. The Planning Committee approves these aforementioned principles. Organized medicine is frequently criticized as opposing group practice. We should like to correct that impression. Medicine does approve group practice, but insists it should be conducted on a highly ethical plane and should conform to such basic principles as those enumerated in *Appendix B*.

The Committee feels, also, that the formation of any group is entirely a local problem and should adapt itself to the situation in each community. We cannot recommend at this time any particular type of group practice.

Compulsory Sickness Insurance—On November 19, 1945, the country was aroused by the presentation to Congress by the President of the most comprehensive and revolutionary proposals for a national health program ever placed before this body. On April 2 last, Senator Taft, at the opening of the hearings on the current Wagner-Murray-Dingell Bill, S-1600, introduced on the same day as the President's program was announced, called this measure "the most socialistic legislation ever introduced to the Congress."

Collectivism raises its ugly head more ominously than ever. To our mind, trends toward national socialism appear to be more evident daily. Let us remind ourselves that this movement for the placement of American medicine under the control of the Federal government through a system of Federal compulsory sickness insurance is an entering wedge toward regimentation of banks, insurance companies, utilities, transportation, industry, and, perhaps, even labor itself.

Provisions 1, 2, 3, and 5 of the President's program, with certain constructive amendments, organized medicine will support. It is Section 4 on this program to be implemented by the current Wagner-Murray-Dingell Bill to which we are unalterably opposed. Title 2 of the National Health Act of 1945, carrying the caption "Prepaid Personal Health Service Benefits," is not materially dissimilar, except for provisions for financing the program, from the comparable sections contained in S-1050. The new bill imposes no taxes. The program it contemplates will be financed, at least as far as the present provisions of the bill are concerned, by appropriations from the general fund.

Nothing has occurred since the previous report of this committee to alter our stand on compulsory sickness insurance.

The President in his Health Message and the new Wagner-Murray-Dingell Bill have both called for compulsory sickness insurance, and both the President and authors of this bill insist that the program is not socialized medicine.

Careful examination of the proposal, however, indicates that it is just that. The program calls eventually for compulsory insurance to cover practically the whole population. It provides for lay administration of medicine, in that in the last analysis the Federal Security Administrator and the Social Security Board are the regulating agents. Once again, the Surgeon General of the United States Public Health Service is designated as the Administrator of the program, but he is subject to the above agencies. The so-called Advisory Board is appointed by him and it has no authority.

The free choice of physician provided in the program is no free choice at all. It offers free choice only if the physicians take part in the scheme. It is free choice if he takes part, only if his panel is not filled. If the majority of the physicians in an area elect to be paid on a capitation basis, it can be operated only by assigning people in a certain district to a certain physician. Here, again, there can be no free choice.

The statement that the physicians will decide how they will be paid is again an inaccurate statement. The majority of the physicians may decide. The minority, no matter how large that minority must abide by the will of the majority.

The patient has no voice whatever in the selection of a specialist. Whether or not he may have one is decided by a government agency.

Regulations governing patients, hospitals, and physicians are promulgated by the Administrator—again a case of rule by administrative law.

A tremendous bureaucracy will be set up with its consequent red tape and inefficiency. There is no premium on good medical care, only on quantity. Medical care will deteriorate. The Government collects money, pays it out, and prescribes the regulations under which physicians, patients, and hospitals operate. Whether it should be termed 'socialized medicine' or 'political medicine' is unimportant. It is regimentation.

The costs of the program are cleverly avoided in the latest version of the Wagner-Murray-Dingell Bill. The President suggested a four per cent payroll tax up to \$3,600. The previous Wagner-Murray-Dingell Bill called for an 8 per cent payroll tax, 4 per cent from the employer and 4 per cent from the employee and a 5 per cent tax from the self-employed up to \$3,600 income. Of this, 3 per cent of the 8 per cent was to be devoted to medical care. Under either suggestion it calls for expenditures of billions of dollars with no guarantee of efficient disbursement for good medical care.

The Committee disapproves any form of compulsory sickness insurance. The needs of the country can be met by an improvement in the economic status of certain groups, by extending public health and preventive medicine facilities, by increasing maternal and child health where needed, by increasing hospital and diagnostic facilities as needed, by the use of Federal funds to provide or extend these facilities where the state or local community cannot afford to provide them, the local communities to have supervision over the agencies created and finally by extending the prepayment of both hospital and medical care costs on a voluntary insurance basis.

The American Medical Association in 1945 adopted a 14-point program for improving the medical care situation in the United States. In 1946 it extended and clarified that program by the adoption of a ten point Health Program. (See Appendix C)

Your Planning Committee again reaffirms the Society's previous stand against compulsory sickness

insurance in general, and disapproval of the current Wagner-Murray-Dingell Bill, S-1600. We recommend the endorsement of this ten point program of the American Medical Association by the House of Delegates.

Public Relations and Medical Publicity—Apropos of the above statement on the Wagner-Murray-Dingell Bill, it seems most timely to the Committee that the distribution of a brochure or some other type of leaflet for public consumption, presenting clearly our points of view and the stand of the Medical Society of the State of New York, should be accomplished as promptly as possible. We continually tell the doctors all this but the public has had only one side of this most controversial subject. We should like, for the information of the Reference Committee and the House, briefly to summarize some of the discussion that the Committee has held regarding suitable publicity for these important matters.

Mr Dwight Anderson, our Public Relations Officer, attended the last meeting of the Planning Committee and he was in thorough accord with the idea and spoke frankly and tersely in favor of it. To quote him "I thought this statement on the Wagner-Murray-Dingell Bill was a perfect brief indictment of this measure which could be understood by anybody." He then expanded his ideas in some detail and suggested methods for implementing this project.

The Committee was privileged to have present at its April meeting Dr Joseph Lawrence, our former Executive Officer and now in charge of the Washington office of the Council on Medical Service and Public Relations of the American Medical Association. He contributed a number of practical suggestions which tended to clarify our thinking, and gave us the benefit of some of his experiences at the national level.

He expressed the opinion that "the sentiment is pretty general over the United States that people do not want things thrust upon them and especially not when they are thrust on them because it is said they could not themselves provide them. They would much rather try to provide for themselves. We particularly hear that is so through the Farm Bureau groups and other groups of that kind from the grass roots. They would rather have what they can provide for themselves than to take these grand conditions or things that are going to be thrust upon them." This was also the principle that actuated the Kelllogg Foundation in their collaboration in the rural hospital programs so successfully accomplished in Michigan and to which we referred at some length in the 1945 report. Their experience taught them that local professional and lay people concerned with social conditions had definite ideas as to what their problems were and what they wanted to do about them. They were more or less alive to their responsibilities and were equally cognizant of their deficiencies in training to meet their community obligations. They began, therefore, with the problems which the people recognized, rather than with those that someone else thought they ought to see. This meant education, and there was elaborated a definite method by which these people could study their problems, exchange experience, talk with others who had solved similar problems successfully and find their own answers through cooperative community action. Local opposition to arbitrary placement of hospitals or other facilities which run counter to their own ideas and plans will be stubborn.

The striking success of the State Society's anti-division campaign proved beyond question the

effectiveness of a well-organized and well-conceived public relations job. Your Planning Committee has in mind some sort of similar program on matters of general health, the practice of medicine, and more particularly at this time, on the Wagner-Murray-Dingell Bill. More and more questions are being brought to Congressmen and state legislators by their constituents, many of them of varied scope, and while often they represent generalizations they are based on specific instances in their own communities.

Medical publicity is an essential part of public relations. We need at the present time some way of conveying our programs to the people who would be friendly to us. These things must be done in a popular way, that is, written up in a popular form so that the people are ready to read them. It may seem to some of you that this is not dignified nor seemly, but we have now reached the point where we have to rely on public support. Government bureaus are sending out pamphlets all the time, stressing their own points of view, never ours. For example, note the booklets from the Department of Agriculture, from the Children's Bureau, from the Public Health Service, etc., which may be had just by writing in for them. We ought to have some ourselves to counteract the pernicious propaganda they are spreading. We should make more use of our statistics, interpreting them in our language.

We are in favor of an adult education program for all of the people in the community who have anything to do with health, education, recreation, or welfare.

We are aware that to make available to the laity material in a form which they will understand will, of course, create additional expense for the Public Relations Bureau. The bureau cannot do these things without additional funds, yet it is highly important that something of this sort be done. Such education of the public as will bring to them the truth about many of these matters and will clearly show what we are trying to do in the public interest should be heartily endorsed and encouraged.

We recommend to the House of Delegates that they make available for distribution to the laity educational or other suitable material on pertinent medical problems, and, specifically, the Society's position on the Wagner-Murray-Dingell Bills, and that the House instruct the Public Relations Bureau to prepare such material for the education of the public and we further recommend that the House invite the attention of the Council and the Board of Trustees to this proposal, reminding them that the Public Relations Bureau cannot do this without the appropriation of additional funds, to the end that this program can be implemented with the least possible delay.

Industrial Medicine—Your Planning Committee is cognizant of the increasing importance of Industrial Medicine and its relation to the practice of medicine. We feel that organized medicine should be very active in this field. The individual medical practitioner should be reminded that he is potentially an industrial physician, that he should evince more interest in the study of the whole health problem concerning the different diseases peculiar to industry.

We should restate here the tremendous amount of work and planning that the American Medical Association has done on this subject through its Council on Industrial Health. We would reiterate the following from last year's report.

1 Your Planning Committee again invites

attention to the Industrial Medicine program of the American Medical Association for state and county societies.

2 We would recommend to the Postwar Planning Committees of the state and county societies that they bring to the attention of physicians returning from the military services the facilities offered in the field of industrial medicine.

3 We would respectfully suggest to those responsible for undergraduate medical education that those diseases and afflictions peculiar to industry be given adequate recognition in their teaching program.

4 We recommend that the Council give this program its serious attention and urge upon the various county societies their cooperation in carrying out this program.

Miscellaneous Topics—As a result of studies and recommendations of the Planning Committee during the past two years, the State Society has set up its Bureau of Medical Care Insurance, with Mr. George P. Farrell as its director. It also was instrumental in causing to be established the Special Committee on the Relationship of the Hospitals to the Practice of Medicine, of which Dr. Carlton Wertz is chairman. We have directed the policy of the Society to a large degree in its pronouncements against the compulsory sickness insurance program. Your Committee has also devoted considerable time and study to such subjects as the nursing problem, medical education and licensure, physical medicine, and the problem of the care of the chronically ill.

Nothing has occurred since the last annual report of this Committee to add substantially to our knowledge of these topics. We would refer those interested to the last two annual reports of the Committee.

As many of the studies now on the agenda of your Planning Committee are continuing programs, we respectfully petition the House that the life of this Committee be extended and that the House authorize the reappointment of this Committee on the same basis as previously provided, and that in addition the Committee be authorized to invite members of Government or other agencies concerned with health problems to sit with the Committee from time to time whenever problems pertaining to their departments arise.

Appendix A

New York State Plan for Survey of Hospital Facilities and Program for Regional Hospital Planning for Postwar Hospital Construction and

New York State Postwar Public Works Planning Commission Joint Hospital Board

ROBERT T. LANDSDALE, *Chairman*
(State Office Building, Albany, New York)

February 15, 1946

Plan for Survey of Hospital Facilities and Regional Planning for Postwar Hospital Construction

In order to meet the requirements of the proposed Hill-Burton Bill, S-191, and to more efficiently plan for postwar hospital construction, the Postwar Public Works Planning Commission, through its Joint Hospital Board, is inaugurating an intensive survey of existing facilities and an appraisal of needed hospital construction.

To secure the assistance and advice available through individuals and groups responsible for the construction, operation, and use of hospitals, the work is to be approached on a regional basis.

For the purpose of facilitating the completion of the survey and for postwar hospital construction planning, the State will be provisionally divided into hospital regions and primary and secondary service districts within each region.

Representatives from each of the primary and secondary hospital service districts will be chosen at regional meetings to which will be invited all hospital administrators and others with interest and responsibility for hospital care. With the hospital service district representatives as a nucleus of the membership, Regional Hospital Planning Councils will be established in each of the regions.

This joint local and state action should result in an orderly and intelligent solution to the problem of meeting the needs for additional hospital and related facilities for the care of the sick.

The following is a résumé of the plan adopted by the Joint Hospital Board.

1 Purpose of the Joint Hospital Board of the New York State Postwar Public Works Planning Commission

1. To inventory the existing hospitals of every character.

2. To survey the need for the construction of hospitals.

3. To develop programs for the construction of such public and nonprofit hospitals as will afford in conjunction with existing facilities, the necessary physical facilities for furnishing adequate hospital clinic and similar service to all of the people.

II State Organization

1. The Governor has designated the New York State Postwar Public Works Planning Commission to act as the sole state agency. The Joint Hospital Board, consisting of the Commissioners of Health, Mental Hygiene and Social Welfare, is to assist and cooperate.

2. A State Advisory Council to the Postwar Public Works Planning Commission is being appointed and will be under the chairmanship of Assemblyman Lee B. Mailler, who has been designated by the Governor as Advisor to the Joint Hospital Board.

III Regional Hospital Plan for the State

(A) Purpose

1. To provide a decentralized method of completing the survey of hospitals.

2. To make available the results of the Survey to the local individuals and groups with responsibilities for hospital care.

3. To provide, through Regional Hospital Planning Councils, appraisals of existing facilities for hospital care.

4. To secure regional recommendations regarding the need for additional facilities.

5. To assist hospitals in their plans for expansion by coordinated regional hospital planning and to enhance working relationships between individual hospitals and services.

6. To take advantage of the position of the four upstate medical teaching institutions for improving facilities for undergraduate and postgraduate medical public health, and nursing education and for the provision of an adequate distribution of medical services requiring specialty training.

7. Through the work of the regional Hospital Planning Councils to assist the Joint Hospital

Board and the New York State Postwar Public Works Planning Commission in meeting its responsibilities.

(B) Organization

1. The provisional division of the state (exclusive of New York City) into four major hospital regions and two smaller regions for the extra metropolitan area.

2. The provisional division of each region into primary and secondary hospital service districts.

3. The Hospital Council of Greater New York, with its Postwar Hospital Planning Committee, and with the cooperation of the Greater New York Hospital Association, will act as the clearing house for New York City.

4. Establishment of Regional Hospital Planning Councils in each of the upstate regions. Regional Hospital Planning Councils should be composed of the hospital administrators, acting as representatives of the primary and secondary hospital districts, representatives of the New York State Hospital Association and its local hospital councils, boards of trustees of hospitals, representatives of the medical and nursing professions, the medical school and representatives of public health, public welfare, agriculture, labor and industry.

5. The appointment of a competent hospital administrator on a full or part-time basis, for a temporary period, for each of the Regional Planning Councils to act as secretary to Regional Planning Councils and to assist in completing the hospital inventory schedules. State funds will be available to cover this service and travel expenses.

6. One local hospital administrator from each of the hospital districts will be asked to volunteer as the representative of his hospital service district and to assist the local hospitals in completing the inventory schedules. This will mean that no one volunteer would be responsible for more than 10 or 12 institutions. These district representatives will receive instruction concerning the interpretation of the inventory schedules from the secretaries of the Regional Hospital Planning Councils and the Joint Hospital Board.

(C) Operation of the Plan

1. The 22-page inventory schedule will be sent directly to each of the hospitals of more than 25-bed capacity.

Hospitals of less than 25 beds will receive a short 9-page inventory schedule in duplicate.

Two copies of the schedule are to be completed, the hospital will retain one for its own use, the second copy will be turned over to the representative of the hospital service district, who will review it with the hospital superintendent, if necessary.

The secretaries to the Regional Planning Councils will meet with the hospital service district representative, check the schedules for the several hospitals within the district, and forward them to the Joint Hospital Board at Albany.

The Hospital Council of Greater New York will distribute the inventory schedules and complete the contacts with hospitals in New York City. Inventory schedules for maternity homes, nursing homes, and related institutions will be completed with the assistance of the several state departments concerned.

2. The completed inventory schedules will be forwarded to Chicago where the Commission on Hospital Care has volunteered to perform the coding, preparation of punch cards, and preliminary tabulations.

The statistical tabulations and completed inventory schedules and punch cards will then be returned for appraisal and planning uses in New York State

3 Shortly after the inventory schedules have been mailed to the hospitals, organizational meetings will be held in each of the regions. To these meetings will be invited representatives of the New York State Hospital Association and its local Councils, trustees, and superintendents of hospitals in the regions, representatives of the medical and nursing professions, the Deans of the Medical Schools and representatives of public Health and social welfare, agriculture, labor, and industry

At the regional organization meetings, the Regional Hospital Planning Councils are to be established, a secretary appointed, and the survey inaugurated. Each Regional Hospital Planning Council should be composed of the hospital service district representatives and representatives of the groups enumerated above

4 Subsequent meetings of the Regional Planning Councils are to be arranged through its chairman, as necessary and by request of the Joint Hospital Board

The Joint Hospital Board will make available to each of the Regional Hospital Planning Councils information secured through the survey and data pertaining to the social and economic factors in hospital planning

Appendix B

Principles for Group Practice Approved by the Coordinating Council of the Five-County Medical Societies, November 1, 1945

1 A medical group shall be defined as a number of licensed physicians engaged in the practice of medicine in a common organization, qualified to provide complete medical care as required, whether this care be in the patient's home, physician's office, or in the hospital

2 All features of medical service in any method of medical practice shall be under the control of the medical profession

3 Physicians may work whole or part-time for an approved group. Where there is only a small demand for a specialist's services, he may serve two or more approved groups

4 Patients may obtain the services of approved groups according to one of two methods

- (a) Through an insurance plan approved by the county medical society in which the group operates
- (b) By payment of fees for services. In the latter case, such fees shall not be lower than the established Workmen's Compensation Schedule fees

5 No third party may be permitted to come between the patient and his physician in any medical relation. All responsibility for the character of medical service must be borne by the medical profession.

6 A patient shall be free to choose any group or individual practitioner of medicine

7 Any method of rendering medical service must retain a permanent, confidential relationship between the patient and a family physician, either as an individual practitioner of medicine or a member of a group

8 Medical care shall be under medical control. Hospital services shall be controlled separately

9 The chief executive officer in charge of ad-

ministration of the medical policy of an approved group shall be a physician

10 The organization and operation of all approved medical groups shall emphasize preventive medicine.

11 Physicians serving in approved groups are to be allowed to assume only responsibilities in the care of patients for which they are qualified according to standards established by the county medical societies

12 Staff conferences of approved groups shall be held at regular intervals

13 No approved group shall provide for payment of commissions or fees to any one for referring patients to the group

14 Chapter II, Section 4, of the Principles of Medical Ethics of the American Medical Association, states "Solicitation of patients by physicians as individuals, or collectively in groups by whatsoever name these be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional"

It is equally unprofessional to procure patients by indirection through solicitors or agents of any kind or by indirect advertisement, or by furnishing or inspiring newspaper or magazine comments concerning cases in which the physician (or group) has been or is concerned. This principle shall apply to any approved group

15 Income which accrues from the group practice of medicine shall, after necessary expenses are paid, be paid to physicians working in the group and not to any other organization or individual

The following has been suggested as an addition by the Queens County Medical Society: Groups having members who are not members of county medical societies may secure the approval of the county society upon their application for such approval.

Appendix C

National Health Program of the American Medical Association

(Promulgated February 23, 1946, by the Board of Trustees of the American Medical Association)

The following is the restatement of the 14-point program of the American Medical Association adopted by the Board of Trustees on February 23, 1946, which clarifies still further the position of the American Medical Association on some of these points, and brings into the program more definitely maternal and child welfare, medical research, medical care of the veteran, and the part to be played by the voluntary health agencies

1 The American Medical Association urges a minimum standard of nutrition, housing, clothing, and recreation as fundamental to good health and as an objective to be achieved in any suitable health program. The responsibility for attainment of this standard should be placed as far as possible on the individual but the application of community effort, compatible with the maintenance of free enterprise, should be encouraged with governmental aid where needed

2 The provision of preventive medical service through professionally competent health departments with sufficient staff and equipment to meet community needs is recognized as essential in a health program. The principle of Federal aid through provision of funds or personnel is recognized with the understanding that local areas shall control their own agencies as has been established in the field of education. Health departments should not assume the care of the sick as a function, since ad-

ministration of medical care under such auspices tends to a deterioration in the quality of the service rendered. Medical care to those unable to provide for themselves is best administered by local and private agencies with the aid of public funds when needed. This program for national health should include the administration of medical care, including hospitalization to all those needing it but unable to pay, such medical care to be provided preferably by a physician of the patient's choice with funds provided by local agencies with the assistance of Federal funds when necessary.

3 The procedures established by modern medicine for advice to the prospective mother and for adequate care in childbirth should be made available to all at a price that they can afford to pay. When local funds are lacking for the care of those unable to pay, Federal aid should be supplied with the funds administered through local or state agencies.

4 The child should have throughout infancy proper attention, including scientific nutrition, immunization against preventable disease, and other services included in infant welfare. Such services are best supplied by personal contact between the mother and the individual physician, but may be provided through child care and infant welfare stations administered under local auspices with support by tax funds whenever the need can be shown.

5 The provision of health and diagnostic centers and hospitals necessary to community needs is an essential of good medical care. Such facilities are preferably supplied by local agencies, including the community, church, and trade agencies which have been responsible for the fine development of facilities for medical care in most American communities up to this time. Where such facilities are unavailable and cannot be supplied through local or state agencies, the Federal government may aid, preferably under a plan which requires that the need be shown and that the community prove its ability to maintain such institutions once they are established (Hill-Burton Bill).

6 A program for medical care within the American system of individual initiative and freedom of enterprise includes the establishment of voluntary nonprofit prepayment plans for the costs of hospitalization (such as the Blue Cross plans) and voluntary nonprofit prepayment plans for medical care (such as those developed by many state and county medical societies). The principles of such insurance contracts should be acceptable to the Council on Medical Service of the American Medical Association and to the authoritative bodies of state medical associations. The evolution of voluntary prepayment insurance against the costs of sickness admits also the utilization of private sickness insurance plans which comply with state regulatory statutes and meet the standards of the Council on Medical Service of the American Medical Association.

7 A program for national health should include the administration of medical care, including hospitalization, to all veterans, such medical care to be provided preferably by a physician of the veteran's choice, with payment by the Veterans Administration through a plan mutually agreed on between the medical association and the Veterans Administration.

8 Research for the advancement of medical science is fundamental in any national health program. The inclusion of medical research in a National Science Foundation such as proposed in pending Federal legislation, is endorsed.

9 The services rendered by volunteer philanthropic health agencies, such as the American Cancer Society, the National Tuberculosis Association, the National Foundation for Infantile Paralysis, Inc., and by philanthropic agencies, such as the Commonwealth Fund and the Rockefeller Foundation and similar bodies, have been of vast benefit to the American people and are a natural outgrowth of the system of free enterprise and democracy that prevail in the United States. Their participation in a national health program should be encouraged, and the growth of such agencies when properly administered should be commended.

10 Fundamental to the promotion of the public health and elevation of illness are widespread education in the field of health and the widest possible dissemination of information regarding the prevention of disease and its treatment by authoritative agencies. Health education should be considered a necessary function of all departments of public health, medical associations, and school authorities.

Section 12 (See 55)

Supplementary Report of the President

SPEAKER BAUER Dr Landy and Dr Azzari, will you form a committee of two to escort the President of the Medical Society of the State of New York to the platform?

(The delegates arose and applauded as Drs. Joseph A. Landy and Renato J. Azzari, of Bronx County escorted Dr. Edward R. Cuniffle to the platform.)

SPEAKER BAUER. Gentlemen, of the last meeting of the House of Delegates, I remarked that so far as I knew this was the first instance in which a President of the Medical Society has been president during two sessions of the House of Delegates. That was due to the fact that our session of 1945 was postponed from its usual time. Therefore, Dr. Cuniffle, to show you how much we think of you and regret your departing we are tolerating you twice. Gentlemen, the President of the Society, Dr. Cuniffle (Applause).

PRESIDENT CUNIFFLE That is a very nice introduction. Thank you very much, Mr. Speaker!

Members of the House of Delegates, sometimes it is hard to start something over again, as you know I asked how to begin a speech one time on the Wagner-Murray-Dingell Bill. It had been talked and mulled over so much, that I was at a loss how to start. The suggestion was, "Well you might tell them a story."

In those days of atomic bombs and various instruments of warfare that have been devised and developed and will destroy practically everything if used there was a bomb dropped over every city, county, state, and hamlet of the world. The powers got double-crossing each other, and they finally got touch buttons to set off these bombs, and everything was destroyed. The earth was nothing but a bare globe. There was not a house or building in it. There was not a tree, there was not a bird. Man was destroyed. Finally out in the Pacific on an island which was devastated, from a cave came a little monkey. He looked around, and could not see a tree or another animal. As he was thinking about it and studying the situation, a female monkey walked out, and he turned around and looked at her and said, "Do we have to start this damned thing all over again?" (Laughter). That is probably the way this shapes up in Speaker Bauer's mind. I have to start this damned thing all over again.

I am very fortunate to be allowed to speak again to this body. This privilege is really a very great honor, for not often does one have the opportunity to address the 140th Annual Meeting of a medical society. It is well to remember that this Society was organized to increase the scientific knowledge of its members, to devise ways and means of achieving better protection of the health of the people of our State and improvement in the quality and delivery of medical care to its citizens. These ideals have been eagerly followed as exemplified by the actions of every meeting of this House, and I am perfectly sure that the present meeting will be no exception.

In my report of the activities of the State Society, I discussed the very vigorous campaign which was waged against the proposed so-called antivivisection bill, calling attention to the good work done by our Committee on Publicity, a work which cannot be praised too highly. This campaign led to the promotion of a national society, called the Friends of Medical Research, with a branch in New York State, under the aegis of the Medical Society of the State of New York and the New York Academy of Medicine. I am not at all sure that this is the best way in which to meet the threat that will again be presented at the next meeting of the Legislature. The national organization is very valuable in the protection that it may give to some of the weak states that are unable to properly protect themselves and, also, in providing scientific men to aid in the educational part of the work. However, I am quite certain that it would be unable to protect our State against the danger of having such a bill being enacted into law. Nor do I believe that an organization in New York City can afford us sufficient protection. It would seem to me that a committee in New York City with only one member from outside the City, no matter how valuable he may be, would present a very weak front for such an important defense. I think it is readily admitted that this is a matter for the entire State. Legislative bills are presented to a legislature composed of representatives elected from every portion of the State. It will be necessary to have men in every county who will discuss this matter and convince the legislators that such an act would weaken and destroy the progress of medicine in our State. It seems to me the part of wisdom for our Society to keep the committees already appointed in several counties and to organize them in counties which have none at present. This framework of committees under the direction of the Council Committee should lead the campaign against such legislation and, of course, accept and encourage the help of any other organization interested.

At the last meeting of the House of Delegates in October, a plea for a universal insurance contract for the State, including surgical, obstetric, and medical care for in-hospital patients was presented to this body. The policy was to be accepted by the different insurance groups of our State. There seems to have been some misunderstanding in what was intended by this policy. It was certainly not intended to interfere in any way with the local policies made to suit the conditions of that locality. The intention was for the medical plans to retain their individual policies but to have one contract that was universal and would be accepted throughout the state. I still believe that this is not only possible, but that it is absolutely necessary if we are to accomplish what we are trying to do with voluntary medical insurance. I trust that this

matter will not be discarded but that the committee having this work in hand will be continued until further study finally decides the question.

The activities toward providing the means of administering the program of the Veterans Administration in regard to the treatment by private physicians of veterans suffering from service-connected disabilities has progressed very favorably. The committee has had several meetings under the chairmanship of Dr. Hale. A fee schedule has been prepared and is ready for presentation to Colonel Harding. Funds have been appropriated by the Board of Trustees and a certificate of incorporation and bylaws of a membership corporation to be formed by the Medical Society of the State of New York for the purpose of dealing with the Veterans Administration has been prepared. The objects and purposes, for which this corporation is formed, are to be promoted, transacted, and earned on without pecuniary profit. The territory in which its operations are principally to be conducted is the State of New York and its principal office is to be located in the Borough of Manhattan, City of New York, State of New York. The directors have been appointed and the certificate will be completed during the next few days. It is well for me to advise the House that it is a vast undertaking that will be very difficult to carry on successfully but that must be done, not alone to show our patriotic feeling of loyalty and gratitude to the veterans, but, also, to prove that our Society can direct and furnish medical care throughout the entire State under this program.

During the past session of our legislature, a large amount of money was appropriated and an extensive program outlined for the construction of county health units throughout the State, to be supervised by fulltime men, and a vigorous attempt was made to completely banish tuberculous disease. I am sure the Society approves very much this plan of improving medical conditions in our State and will earnestly support it.

I would be remiss at this time if I did not call your attention to that part of the report which contains the discussion of the Governor's Commission for the Study of Medical Care. It is well to note the men who signed the majority report, which is a practical endorsement not alone of our criticism of compulsory health insurance but is, also, an approval of the many changes we have been advocating for the past several years. It is well to bear in mind the fact that many matters approved by our Society as being worthwhile are not always adopted and, consequently, are not enacted into law. I must also say a word of praise for the two men of our Society, Dr. Harold Brown, of Buffalo and Dr. Andrew E. Eggston, of Westchester County, who were appointed to the Commission after it was in existence one year, for the very able way in which they represented our Society and the amount of work they were compelled to do on account of their late appointment. I cannot emphasize that too strongly because I know that they completely dominated the Committee with the facts they presented after their appointment, and they deserve a great deal of credit.

After a number of years a society having a great many committees seems to get into trouble with the misunderstanding consequent upon an overlapping of these committees with reduplication of work. Several complaints have been brought to me of this condition in this Society at the present time, and I would like to petition the House of Delegates to

request the Council to appoint a committee to study the system of committees and if it is found necessary, to publish any proposed amendments to the Bylaws in time so they may be acted upon next year.

I want to extend greetings to the incoming President with my very best wishes and forecast for him a very successful administration. I would like to call attention to the very earnest and extremely valuable work of the past-presidents who are among the most active of our members, some of them past-presidents for many years. Such an example would urge us to do likewise and continue to work actively in the affairs of the Society. I pledge my assistance I can give to the incoming president and hope that I can be as valuable to him as the immediate Past-President Dr. Bruckus has been to me.

I have enjoyed very much my year as your President. In spite of the fact that hotel accommodations were not always available and traveling conditions presented some difficulties. However I have been amply repaid for any inconvenience by the pleasure of meeting so many members of our Society. I have a very high opinion—much greater than ever before—of the New York State doctor of medicine. I am thinking not only of his scientific ability but, also, of his sterling character. I have received the most sincere cooperation and assistance from the members of all the committees and of course, have been guided, advised and ruled by the Council whose loyalty and helpfulness I appreciate more than I can say. I am sure that no organization exists with higher ideals and ethics, which means honesty and uprightness in dealing with all.

Thank you very much! (Applause)

SPEAKER BAUER Thank you, Dr. Cunniff! I hope you are going to remain on the platform throughout the session.

The remarks of the President are referred to the Reference Committee on the Report of the President.

Section 13 (See 55)

Report of the President-Elect

SPEAKER BAUER Dr. McKendree and Dr. Golly, will you form a committee of two to escort the President-Elect of the Medical Society of the State of New York to the platform?

(The delegates arose and applauded as Drs. Oswald J. McKendree and Bradford F. Golly of Oneida County, escorted Dr. William Hale to the platform.)

SPEAKER BAUER Members of the House, I feel that Dr. Hale is really entitled to two introductions. I say that for this reason. It has always been customary after a man has been elected President-Elect to escort him to the platform and present him to the House. Last year you will recall that our closing session was pretty hectic. In fact, it was so hectic that we did not even have time for one report which had to be read by title only. Therefore, there was no opportunity to present him at that time. I regret that so I am going to introduce him twice now, once for last October and again now, gentlemen, the President-Elect, Dr. William Hale. (Applause)

PRESIDENT-ELECT HALE Mr. Speaker thanks for both introductions.

One cannot be in this House very long without appreciating that there is a tremendous amount of business being transacted. I am reminded of a story that was told by one of the visitors at the House of Delegates meeting of the American Medical Association. He was referring to some of the boys overseas in uniform who when they had

an opportunity, visited the neighboring towns to see what was going on. In one of these towns a lad looked up at a fine brick building turned to a man in the street and said, "Hey, Bo, what is this building?"

"Oh, that's our crematorium."

"Gee whiz, is that where they make cheese?"

"Oh, no, no go inside and have a look."

So the lad went inside, and after about two minutes he landed out on the sidewalk on all fours. The man picked him up and said, "What happened to you?"

"I don't know but I went inside, and I saw this grand big building, and over in one corner there were a bunch of sourpusses so I went over and slapped a couple of them on the back and said, 'Hey Bos what's cooking?' (Laughter)

There's no question but that there's a lot cooking here, and from some of the committee meetings that I happened in on yesterday, I think we are going to require three days for this session.

I should express my gratitude to this House for the confidence they have placed in me by electing me to this office. I certainly do appreciate it. I want to assure you that I think this Society is run by every member of this House of Delegates. Your officers are constantly looking for advice from the entire membership. During the months when you are not assembled, it is your representatives in the form of the Council that carry the advice to your presiding officer. That advice has been excellent in the past, and I know I am going to need that same type of advice in the next few months. I anticipate your support in every way, and I assure you I will do my utmost to carry out the wishes of this House and of your Council.

We meet today in an atmosphere of hope and challenge. At no other time in medical history have there been so many problems demanding action by the medical profession and inviting the interest of individual practitioners as we have at this time. During the war, our greatest interest was with the recruitment of necessary personnel in order to have the best that medical science could give to the men and women upon whom we depended to win one of the bitterest wars the world has ever seen. Now we must turn our attention to the needs of a peacetime society.

At no other time has the profession needed so urgently to stand firm and united. The threat of government-controlled health insurance is still making itself felt in no uncertain way. Hearings have been held during the past month on the third Wagner-Murray-Dingell Bill in a period of three years. As physicians who are vitally involved in medical care we know the danger to which both our patients and ourselves will be exposed should this mammoth bureaucratic plan be foisted upon our country. Not one of us can be unconcerned, for it would touch on the lives of every person from coast to coast. The doctor certainly would be effected by the inevitable red tape, with the issuance of orders from lay administrators, the changing of responsibility from the patient to the government bureau. Medical care would no longer be in the hands of the medical profession.

The patient would by the same token suffer from the mediocrity which is the very core of compulsory health insurance. He would be required to pay large sums into the health insurance treasury but he would have very little to show for it. The quality or quantity of medical care would be determined by the amount of money he could pay.

patient and physician would be gone. Scorned as this patient-physician relationship has been by the proponents of socialized medicine, we know that in the majority of cases it is the very cornerstone of success in dealing with the sick person.

The cost of a compulsory health insurance program we can guess. Not only would there be a payroll tax, but there would also be a drain on the general treasury, the sum of which cannot possibly be estimated. Perhaps such a blank check would not be too high a price for the American people to pay for a sure return, but to sign such a blank check for a kind of medical care which, in short order, would be ridden with politics, is tragedy indeed.

The Medical Society of the State of New York has not been content merely to warn the people against political medicine. My predecessors have given leadership to the movement within our State to establish adequate facilities for prepaid medical care insurance. Today, we have six plans in operation throughout the State of New York under Medical Society sponsorship. This development has come within the comparatively short period of six years. We intend to continue to strengthen these plans and to extend them so that every person in New York State will know that this coverage is available. Employers will know more and more that they can offer medical care protection to their employees just as they now can offer hospital care protection.

While we continue to promote the various plans in our own state, we have the additional responsibility, this year, of coordinating them with the over-all national plan which the American Medical Association launched several months ago. Perhaps, in this way, we can help to put across the ideal of non-profit medical care insurance to the entire nation. We owe every cooperation to this purpose and we will give it.

In connection with voluntary medical care insurance, we think inevitably of the veteran of this war who has been promised medical care by the Veterans Administration. The Veterans Administration has shown great interest in a plan by which veterans may be able to secure needed medical care from their own home town physicians and in their own hospitals. Already arrangements have been made with several state medical societies and negotiations are in process with others. Your President has referred to the work that has already been done under his administration, and I trust that work will continue during the next year. The Medical Society of the State of New York has already held conferences with officials of the Veterans Administration several months ago, and studied this question in great detail. We have been truly concerned that the veteran should receive his due without his becoming a political football to be kicked around. He should receive the medical care to which he is entitled, in a way which will completely assure him his dignity as an individual. We hope to work out these negotiations with the Veterans Administration so that every doctor in the State may provide medical care for veterans who are his patients. You will hear much more about this in the coming months.

I would like to mention here the work of Major General Hawley in providing first-class medical care for veterans. From the time of his appointment he was determined to keep veterans' medical care out of politics. In the past, veterans' hospitals have been located too often according to the needs of political patronage. General Hawley, however, is determined that they shall be located in areas which offer the best medical facilities and the best

medical personnel. You may well imagine that this has not been easy for him. Politics intrude even on so sacred a matter as the medical care of men who sacrificed much for their country and to whom we acknowledge a great debt of gratitude. I am sure that every one of us as individuals, and the Society as a professional organization, assures General Hawley of every support we can give him in his program.

We cannot talk about veterans of this war without remembering members of our own profession who have been in the armed service. The medical profession looks with pride upon the accomplishments of these men. Many are still serving the peacetime needs of the Army and Navy.

Many physicians found a great opportunity for service during the war. Every new advance known to medical science, all the skill developed over years of practice, went with them when they became physician-soldiers. All the advantages resulting from our high educational standards in medicine were put at the command of the armed services.

It is true that many physicians did not find military service rewarding. They had the same amount of skill, the same devotion, and the same energy as the others, but in the allotment of tasks in a period of great pressures and preparation for great emergencies they were often in positions where they had little or no opportunity to give what they had to offer. For many this was a bitter disappointment.

Doctors in service have been returning in the past six months, slowly to be sure, but returning. In many cases they can slip back into practice with a minimum of effort. In far more cases they come home to find their practice practically gone, no office space to be had, almost no equipment obtainable. In many instances, they can find neither office space nor living space for their families. Both individually and as a Society, we have a deep obligation to these men who are finding it difficult to become re-established.

The Medical Society of the State of New York has rendered considerable service by giving returning physicians information as to refresher courses, residencies, and partnerships available. It has also been able to give information about practices which might be taken over. It has kept in touch with co-operative agencies which could direct physicians to parts of the State and, sometimes, to locations outside the State which needed physicians.

I believe every county society should re-examine its program to assist returning doctors who are striving to assume their rightful places in their profession, and to change or augment that program in the light of their experiences during the past six months or so. I also urge every physician who has cared for patients whose doctors have been to war to return those patients to the physician who is now trying to find his way back again.

There is one subject which will draw much discussion from this House, namely the American Cancer Society, which is in the process of a campaign for a large sum of money. We have a committee of this Medical Society, and we should have a committee in each component county society, to partake of this great problem. It is proposed to spend 60 per cent of the money raised in the state where it was subscribed, and it is to be spent directly for service to the cancer patient. This may go far in keeping the control of the cancer problem from the hands of the uninformed.

As President of the Medical Society of the State of

New York, I do not plan to carry the torch for any particular interest of my own. Rather, it is my purpose to try to reflect the interests of every physician in our State and to represent those interests well. In this, I hope for the cooperation of every individual physician and of every constituent medical society. Only thus can I serve well as President of your State Society. (Applause)

SPEAKER BAUER The remarks of the President-Elect are referred to the Reference Committee on the Report of the President.

Dr Hale, in the five years you were Vice-Speaker, I am sure you took root up here and would not feel at home anywhere else, so I hope you will remain here during the session.

PRESIDENT ELECT HALE Thank you, sir

Section 14 (See 67)

Introduction of Representatives from Other State Societies

SPEAKER BAUER Are there any delegates here from the States of Connecticut, New Jersey, or Vermont?

(There was no response)

SPEAKER BAUER If any delegate discovers there are such present at any time during the session, the Chair would appreciate it if you would call his attention to them.

Section 15

Introduction of New Members of House of Delegates

SPEAKER BAUER Are there any new members present who have never sat in this House before? (Approximately 18 delegates arose.)

SPEAKER BAUER We are very glad to have you here. I am sure you will find that you are most cordially welcomed by the older delegates. We hope that you will feel free to take part in our discussions at any time if you have anything to say. Seniority in the House is not necessary to get the attention of the chair.

Section 16

Presentation of Dr Joseph S Lawrence to the House

SPEAKER BAUER We have this morning a very distinguished gentleman present, whom I am sure the House wants to welcome. It seems funny to think of him as a guest when for twenty-one years he was Executive Officer of the Medical Society of the State of New York. He left us to enter a larger field as Director of the Washington Office of the Council on Medical Service and Public Relations of the American Medical Association. He was very successful here when he served us, and he is becoming equally successful in Washington as all of us who knew him were sure he would. If I should say I was going to introduce Joe, some people might not know whom I meant, but if I said Joe Lawrence, I think there is no one in the room who would not know him, so Joe, come up here and greet a lot of old friends. (Applause)

Dr. JOSEPH LAWRENCE Mr Speaker and Friends of the Medical Society of the State of New York, you cannot imagine how happy I am and how honored I am in being asked to come before you. Just to look you in the face again is a pleasure. As your Speaker said, for twenty-one years I never missed a meeting of this House, but I sat in the back row somewhere listening to what you were saying and going along with you.

I know that you are going to be a busy body today

You have a lot of work in front of you. I could probably entertain you for half an hour, but I am not going to do it. From here, however, I should like to say that while I am here, if any of the Reference Committees wants to talk with me about things that are happening in Washington—and there are plenty—I will be at their service, and delighted to tell them what I know about the subject under inquiry. However, I cannot before sitting down refrain from that old habit of mine, which my wife says was born in me as a schoolteacher, and that is I must tell people what to do. There is just one thing I would like to mention to you and that is, in your deliberations this week, be realistic. You know what that means being realistic. I think we have reached the point where we have got to be realistic. Let us pick up two or three things that need doing, but be realistic in our approach.

I thank you again for your attention and for the pleasure of being here. (Applause)

SPEAKER BAUER Thank you very much!

(Further Announcements regarding times of meeting of various Reference Committees, as well as places of meeting)

Section 17

Appointment of Committee on Scientific Awards

SPEAKER BAUER The President announces the Committee on Scientific Awards to consist of Dr George C. Adie, Dr Abraham H Aaron, and Dr Alfred M. Hellman.

The floor is now open for the introduction of resolutions.

Section 18 (See 60)

Study of Advisability for the Establishment of Minimum Medical-Surgical Fee Schedule

Dr. JOHN C. BRADY, Erie This is introduced on behalf of the Erie County Medical Society.

"WHEREAS, in many quarters of New York State there is a swelling demand from medical organizations and practitioners for the establishment of a schedule of minimum charges and fees for diagnostic, medical, and surgical services, and
"WHEREAS, it is the considered judgment of these professional elements that such a minimum schedule would

(1) Serve to set an absolute minimum charge for each type of care or service thereby curbing or minimizing unfair and unwholesome competitive practices which are especially prevalent in populous communities,

(2) Tend to prevent or reduce criticism of the medical profession for making charges deemed out of proportion to the degree of professional responsibility assumed, the time expended and the financial ability of the patient to pay, and

(3) Eliminate to a substantial degree, the extreme variations in charges for the same type of services among physicians of equal professional competence, and

"WHEREAS, it is recognized that minimum fee schedules for Workmen's Compensation practice and care of persons under voluntary prepayment insurance and Veterans Administration plans are based, to a greater or less degree, upon charges that prevail in the zone or locality for similar treatment of patients of like standards of living, that is, the charges made in private practice, and

"WHEREAS, the adoption of a minimum fee schedule for private practice undoubtedly would further and facilitate the establishment of really

fair and reasonable as well as satisfactory minimum fee schedules for services in the Workmen's Compensation and the other enumerated fields, now, therefore, be it

"Resolved, that the Medical Society of the State of New York, represented in this duly convened session of its House of Delegates, hereby goes on record as favoring and requesting that its Council explore and study fully the necessity and advisability for the establishment

(1) Of a minimum medical-surgical fee schedule for the entire State of New York, or

(2) A series of minimum medical-surgical fee schedules designed for and limited to defined areas of the State, or

(3) A minimum fee schedule for each County of the State "

SPEAKER BAUER That resolution is referred to the Reference Committee on New Business A, of which Dr D'Angelo is Chairman

Section 19

Creation of Membership Classification for Physicians Employed by Veterans Administration or Serving in the Regular Army or Navy Medical Corps

DR SAMUEL B BURK, *New York* The subject of this resolution is the Creation of Membership Classification for Physicians Employed by Veterans Administration or Serving in the Regular Army or Navy Medical Corps

"WHEREAS, a considerable number of American physicians are now being employed by the Veterans Administration on fulltime service or have decided to accept permanent appointments with the medical corps of the regular Army or Navy, and

"WHEREAS, many of these physicians desire to establish and maintain a membership affiliation with organized medicine, and

"WHEREAS, the Constitution and Bylaws of the Medical Society of the State of New York at present makes no provision for a membership classification for these physicians, therefore be it

"Resolved, that Article II of the Constitution of the Medical Society of the State of New York be amended by the addition of the following '(D) Associate', and be it further

"Resolved, that a new section to be designated as Section 8 shall be added to Chapter I of the Bylaws of the Medical Society of the State of New York to read as follows

"Section 8 The Associate Members of this Society shall be graduate physicians who are affiliated fulltime with the Veterans Administration or are serving on permanent appointments in the regular Army or Navy Medical Corps, who are stationed temporarily or indefinitely within the State of New York and who shall have been admitted to a corresponding form of Associate Membership, without vote, in a component county medical society Associate Members of the Medical Society of the State of New York shall pay the regular assessments of the State Society in the same manner as active members The specific requirements for admission as an Associate Member shall be established by each of the component medical societies "

SPEAKER BAUER That resolution, involving an amendment to the Constitution and Bylaws, cannot be referred to a Reference Committee but will re-

main in the hands of the Secretary when, after being duly published, it will come up for consideration next year

Section 20 (See 63)

Group Plan of Malpractice and Defense Insurance—Yearly Audit

DR THOMAS F MCCARTHY, *Bronx* I have three short resolutions to introduce

"WHEREAS, the Bronx County Medical Society sponsors the Group Plan of Malpractice and Defense Insurance of the Medical Society of the State of New York, and

"WHEREAS, as such sponsor, the Bronx County Medical Society is vitally interested in the financial status of the Group Plan, therefore be it

"Resolved, that the House of Delegates of the Medical Society of the State of New York direct that a yearly audit including an inspection of vouchers of the Group Plan be made by a certified public accountant and submitted to the Comitia Minora of each County Medical Society, thirty days previous to the Annual Meeting of the State Medical Society "

SPEAKER BAUER This resolution will be referred to the Reference Committee on Report of Council, Part XII, which deals with Malpractice Defense and Insurance in part, of which Dr Eugene R. Coon is Chairman

Section 21 (See 62)

Group Plan of Malpractice and Defense Insurance—Report from Counsel Re Final Disposition of Malpractice Suits

DR THOMAS F MCCARTHY, *Bronx* The second resolution reads

"WHEREAS, the Bronx County Medical Society is concerned with the final disposition of suits brought against its members for malpractice, therefore be it

"Resolved, that the House of Delegates direct that the Medical Society of the State of New York through its Counsel submit a report to the Comitia Minora of each County Medical Society on the number of members insured in the group plan in said county, number of suits in said county (against insured, against noninsured), number of suits dropped, number of suits settled and amounts, and the number of judgments and amounts "

SPEAKER BAUER This resolution will likewise be referred to the Reference Committee on Report of Council, Part XII, of which Dr Eugene R. Coon is Chairman

Section 22 (See 61)

Group Plan of Malpractice and Defense Insurance—Establishment of Fund for Sole Purpose of Meeting Counsel Fees in Defense of Malpractice Suits

DR THOMAS F MCCARTHY, *Bronx* The third resolution reads

"WHEREAS, the Bronx County Medical Society considers inequitable the present arrangement for the payment for Malpractice Defense of members of the Medical Society of the State of New York therefore be it

"Resolved, that the House of Delegates of the Medical Society of the State of New York direct that a separate and distinct fund be established for the sole purpose of meeting counsel fees in the defense of all malpractice suits against members of the Medical Society of the State of New York."

SPEAKER BAUER This resolution will also be referred to the Reference Committee on Report of Council, Part XII dealing in part with Malpractice Defense and Insurance, of which Dr Eugene R. Coon is Chairman

Section 23 (See 80)

Change in Federal Compensation Act

DR. BENJAMIN M. BERNSTEIN, Kings This resolution concerns itself with a change in the Federal Compensation Act

"WHEREAS, the Federal Compensation Act does not provide for free choice of physician, thereby violating one of the most important tenets in the relationship between doctor and patient, and

"WHEREAS, the New York State Compensation Law has always recognized the necessity for such a regulation and embodies such permission in its provisions, and

"WHEREAS, numerous complaints have been received from our membership because of the difficulties in treating patients injured in Federal service and covered only by the Federal Compensation Act, therefore, be it

"Resolved, that the House of Delegates of the Medical Society of the State of New York memorialize the House of Delegates of the American Medical Association urging that this body advise the proper Federal authorities concerning this provision and urge that a change in the Federal Compensation Act be made to permit all injured persons to go for treatment to a doctor of his or her own choice."

SPEAKER BAUER That resolution is referred to the Reference Committee on New Business of which Dr Frederick W Williams is Chairman, Reference Committee C

Section 24 (See 83)

Establishment of Speakers' Bureaus

DR. BENJAMIN M. BERNSTEIN, Kings The second resolution concerns itself with the establishment of Speakers' Bureaus

"WHEREAS, no organized body can carry forth its message of service to a community without adequate dissemination of knowledge concerning its activities and functions, and

"WHEREAS the trend of the times requires an ever-broadening relationship between the medical profession and the public so that the physician's point of view shall be placed before the public in proper perspective at all times, therefore be it

"Resolved, that a Speakers' Bureau be set up as part of the Council or Committee on Medical Service and Public Relations in county, state, and national societies to act as spokesmen for these bodies, and be it further

"Resolved, that these speakers' bureaus be adequately informed of all phases of medical practice so that a unanimity of opinion might be voiced, and be it further

"Resolved, that all interested lay county state and national associations be apprized of the existence of such a speakers' bureau for use at their meetings, conventions and conferences, on health matters as they effect both the physician and the public."

SPEAKER BAUER Referred to the Reference Committee on New Business A of which Dr Thomas M. D Angelo is Chairman.

Section 25 (See 74)

Establishment of County Health Departments

DR. OLIVER W H MITCHELL Mr Speaker and Members of the House, this is a resolution urging the establishment of County Health Departments

"WHEREAS, the Medical Society of the State of New York is cognizant of the limitations of public health service under part-time health organizations such as now exist in most townships, villages, and small cities of the State, and

"WHEREAS, the State of New York after January 1, 1947, through increased State financial assistance to counties will make it increasingly advantageous for counties to establish and maintain modern health services by organizing a county health department staffed by full-time professionally trained medical and auxiliary personnel on a merit system basis and at the same time permit the retention of local part-time health officers able to demonstrate their value as a part of a county wide organization, and

"WHEREAS, this Society approved on May 9, 1927, the county health department form of organization and subsequently reaffirmed said approval, and

"WHEREAS, the House of Delegates of the American Medical Association on June 10, 1942, passed a resolution urging the establishment of fulltime modern health services to provide complete coverage of the nation's area and population, be it

"Resolved that the House of Delegates of the Medical Society of the State of New York urge the voluntary establishment and maintenance of county health departments throughout the State at the earliest possible date in order that the existing deficiency in public health administration be corrected, and be it further

"Resolved, that a copy of this resolution be sent to the Honorable Thomas E. Dewey Governor of the State of New York, and to the Honorable Edward S. Godfrey, Jr., M.D., Commissioner of Health of the State of New York "

SPEAKER BAUER Referred to the Reference Committee on New Business B of which Dr Leo F Simpson is Chairman

Section 26 (See 83)

Amendment to Principles of Professional Conduct

DR. HAROLD B. DAVIDSON, New York This is the proposal of an amendment to the Principles of Professional Conduct of the Medical Society of the State of New York providing that splitting or refunding of fees in connection with medical care shall constitute unethical conduct

"WHEREAS, it is desirable that the Principles of Professional Conduct of the Medical Society of the State of New York shall be in harmony with the Workmen's Compensation Law and the Education Law with respect to the prescribing of rebates, splitting or refunding of fees, therefore be it

"Resolved, that the Principles of Professional Conduct of the Medical Society of the State of New York shall be amended as follows

"Strike out the second paragraph of Section 32 reading as follows

"Physicians shall not directly or by any subterfuge participate in or be a party to the act of the division, transference assignments, subordination, rebating, splitting, or refunding

'of any fee for medical, surgical, or other treatment'

"Enact and substitute in place of the above deleted paragraph the following

"It shall constitute unethical conduct for a physician directly or indirectly to request, receive, or participate in the division, transference, assignment, rebating, splitting, or refunding of a fee for, or to directly or indirectly request, receive, or profit by means of a credit or other valuable consideration as a commission, discount, or gratuity in connection with the furnishing of medical or surgical care, diagnosis, or treatment or service including x-ray examination and treatment, or fee in connection with the sale, rental, supplying or furnishing of clinical laboratory service or supplies, x-ray, laboratory services or supplies, inhalation therapy service or equipment, ambulance service, hospital or medical supplies, physiotherapy or other therapeutic service or equipment, artificial limbs, teeth or eyes, orthopedic or surgical appliances or supplies, optical appliances, supplies or equipment, devices for aid of hearing, drugs, medication or medical supplies or any other goods, services, or supplies prescribed for medical diagnosis, care or treatment. This shall not preclude a physician making a reasonable payment to a hospital or other medical institution for the use of its facilities in his professional work, nor shall it preclude the organization of physicians in partnerships or groups, provided such organizations are within the laws of the State of New York and are organized and operated in harmony with the Principles of Professional Conduct of the Medical Society of the State of New York."

SPEAKER BAUER That resolution is referred to the Reference Committee on New Business C, of which Dr Frederick W Williams is the Chairman

Section 27 (See 86)

Car Priorities for Veterans (and Other Physicians)

DR. J A LANDY, *Bronx* This resolution is in reference to car priorities for veterans and other physicians as well

"WHEREAS, physician veterans are finding it impossible to obtain automobiles for professional use except under black market conditions, and

"WHEREAS, priorities for physicians have been discontinued, and

"WHEREAS, some automobile manufacturers (Ford) and some district distributors have established a policy of supplying essential users with automobiles, based on the former priority standards, therefore be it

"Resolved, that the House of Delegates of the Medical Society of the State of New York petition the Council to contact the duly constituted governmental bureaus and agencies, acquainting them with the critical situation and urging an official return to priorities for the distribution of automobiles, and be it further

"Resolved, that the House of Delegates of the Medical Society of the State of New York petition the Council to contact automobile manufacturers and district distributors, explaining the urgency of the situation and requesting priority for physician veterans as well as other physicians requiring automobiles for the practice of their profession, and be it further

"Resolved, that the delegates of the Medical Society of the State of New York to the House of Delegates of the American Medical Association be instructed to press for similar measures at the next Annual Session"

SPEAKER BAUER That resolution is referred to the Reference Committee on New Business A, of which Dr Thomas M D'Angelo is Chairman.

Section 28 (See 78)

Remission of Dues for Medical Veterans

DR. EDWIN L HARMON, *Westchester*: This resolution concerns itself with the clarification of the remission of dues' provision for medical veterans

"WHEREAS, there is still confusion in the book-keeping departments of certain county medical societies concerning the remission of dues for veterans, and

"WHEREAS, the present ruling states that

"the existing procedure be revised and liberalized to provide remission by the State Society of its portion of dues for a full twelve-month period plus any additional months necessary to coincide with the fiscal year of the Society", and

"WHEREAS, this ruling allows great inequality in the periods of remission of dues following return to civil practice providing as much as two years for those 'relieved of active duty' in January, 1946, and only one year for those 'relieved of active duty' in December, 1945, now, therefore, be it

"Resolved, that dues for civil practice should be remitted only for the balance of any fiscal year in which less than six months were spent in active military service but where six or more months were spent in active military service, during the year of discharge, remission of dues should extend over the balance of that year plus one additional twelve-month period"

SPEAKER BAUER Referred to the Reference Committee on New Business B, of which Dr Leo F Simpson is Chairman

Are there any further resolutions?

(There was no response)

SPEAKER BAUER In my six years as Speaker, I have never seen so few introduced at the first session. I am very anxious to have as many resolutions as possible introduced this morning because the reference committees have all afternoon and evening to do their work, and if they are not introduced this morning they can only be introduced tomorrow, which means that the reference committees are going to work during the sessions of the House, which I am trying to avoid

CHORUS We are trying to have them typed. We will have some shortly

SPEAKER BAUER I will declare a recess for about five minutes to enable that to be done. Please don't go very far because I want to get all the resolutions introduced this morning that it is possible to do, so that the Committees on New Business will be able to consider them this afternoon and this evening and be ready with their report on them for tomorrow's session

(A short recess was had at this point)

SPEAKER BAUER The House will be in order

Section 29 (See 89)

Publicity for Veterans

DR. FREDERICK W WILLIAMS, *Bronx* I would

like to introduce this resolution on behalf of the Bronx County Medical Society

"WHEREAS, several hundred members of the Medical Society of the State of New York have returned from active military service, and

"WHEREAS, several hundred more are expected to return from military service within the next six months, and

"WHEREAS, these veteran physicians, because of the housing shortage, are being compelled to re-establish practice in neighborhoods where they are unknown, and

"WHEREAS, 50 per cent of their former patients have moved during the past five years leaving no forwarding address, and

"WHEREAS, there is no effective way of reaching this 50 per cent except through public notice that these physicians have resumed private practice, therefore be it

"Resolved, that the House of Delegates of the Medical Society of the State of New York approve newspaper publicity for veteran members by the local medical societies, and be it further

"Resolved, that this publicity be limited to the publication of the names, addresses, and telephone numbers in a local paper for three insertions"

SPEAKER BAUER Referred to the Reference Committee on New Business A, of which Dr Thomas M D Angelo is Chairman.

Section 50 (See 79)

Invitation to American Medical Association for 1949

DR. ROY B HENLINE, *New York* This resolution is from the County Society of New York regarding an invitation to the American Medical Association for 1949

"Resolved, by the Medical Society of the State of New York that a formal invitation be extended to the Board of Trustees and House of Delegates of the American Medical Association to hold the Annual Meeting of the American Medical Association in New York City in 1949"

SPEAKER BAUER Referred to the Reference Committee on New Business C, of which Dr Frederick W Williams is Chairman.

Section 31 (See 82)

Amendment to Principles of Professional Conduct

DR. ALFRED HELLMAN, *New York* This concerns a possible amendment to the Principles of Professional Conduct concerning criticism of one physician by another

"WHEREAS, gratuitous or adverse criticism by a physician of the character of another physician or the quality of professional services rendered by him to a former patient serves no constructive purpose and frequently gives rise to legal action of the nuisance variety against the doctor whose work has been criticized, therefore be it

"Resolved, that a new paragraph shall be added to Section 35 of the Principles of Professional Conduct of the Medical Society of the State of New York reading as follows

"Every physician should refrain from useless and adverse criticism or derogation of the character or quality of the medical services rendered by another physician in the course of his contacts or communications with former patients of another physician."

SPEAKER BAUER There being another resolution

on the subject of the Principles of Professional Conduct, which has already been referred to the Reference Committee on New Business C, of which Dr Frederick W Williams is Chairman, this likewise will be referred to that same Reference Committee

Section 52 (See 43-44)

Upward Revision of Workmen's Compensation Fee Schedule

DR. STANLEY E. ALDERSON, *Albany* This is a resolution from the Medical Society of the County of Albany regarding Workmen's Compensation Fee Schedule

"WHEREAS, the present compensation fee schedule was established in 1938 and has not been increased, and

"WHEREAS, the general costs of living, etc., have increased more than 35 per cent in the same period, and

"WHEREAS, our Compensation Committee has repeatedly called this to the attention of the State Society Compensation Committee, therefore be it

"Resolved that the House of Delegates of the Medical Society of the State of New York hereby requests, through the proper channels, that the entire Workmen's Compensation fee schedule be increased 25 per cent.

SPEAKER BAUER Referred to the Reference Committee on Report of the Council, Part A, having to do with Workmen's Compensation, of which Dr William B Rawls is Chairman.

Section 53 (See 75-103 for Reference Committee Report)

Promotion of National Health—Introduced by Dr A. Wilbur Duryee, *New York*

Section 54. (See 87)

Hospital Training for Professional Graduates

DR. ROGER A. HEMPHILL, *Livingston* This resolution concerns hospital training for professional graduates

"WHEREAS, hospital experience is universally recognized as a basic part of professional training, and

"WHEREAS, such training is not at present required by our Medical Practice Act, be it

"Resolved, that the House of Delegates actively promote legislation requiring the Medical Practice Board to grant a license only to those who have spent a year after graduation in a hospital approved by the Board of Regents"

Notice that the wording does not limit this specifically to the medical man, but refers to the Medical Practice Act. We feel in our County that hospital experience is something everybody licensed under the Medical Practice Act ought to have after he has completed his professional education. It is not, at present, required of physicians or anyone else. Since other than physicians can now practice medicine, possibly it might be advisable to make it mandatory for all to take that, whether physicians or not.

SPEAKER BAUER That resolution is referred to the Reference Committee on New Business A, of which Dr Thomas M D Angelo is Chairman.

Section 55 (See 75)

Session on Chest Diseases

DR. HERBERT E. WELLS, *Erie* This is a resolution asking for a Session on Chest Diseases

THE GRADUATE SCHOOL IN MATHEMATICAL PHYSICS AT BIRMINGHAM

IN 1956, a Graduate School in Mathematical Physics, leading to a diploma, was instituted in the Department of Mathematical Physics of the University of Birmingham. It had been noticed that students who graduated in the honours school of mathematical physics in the Department seemed well equipped, and considerably in demand, for work involving the applications of mathematics to physical problems in industry, government laboratories, etc., because of the training they received in the principles of physics, and particularly in the techniques of translating physical problems into mathematical terms, and of interpreting the solutions from a physical point of view.

Entry to the honours course at Birmingham is restricted to students of high ability, who must have the appropriate background in their school training, since the three-year course makes fairly heavy demands on the students. It seemed likely therefore that a one-year postgraduate course would be of advantage to students who had taken a degree in mathematics, because they could not—or did not choose to—enter the mathematical physics course, or who graduated from universities at which such a course was not available.

The three years of operation of the Graduate School have provided sufficient experience to judge that it can serve the purpose for which it was intended, and that it imparts to the students knowledge and experience which serves them well in their later work. The course extends over one academic year (October to July) and is normally intended for honours graduates in mathematics with subsidiary physics. In some cases it proved possible to fit in students with somewhat different qualifications. Lecture courses attended by the students include a course in methods of mathematical physics (given so far by Dr J. G. Valatin, who is in general charge of the Graduate School), which forms the central theme of

their introduction to the outlook of a mathematical physicist. In addition, students normally take selected parts of the lecture courses for honours physicists, and those parts of the final-year course for mathematical physicists (electromagnetic theory, hydrodynamics, quantum mechanics) which they have not previously covered, and which suit their particular needs. Other options include mathematical statistics, numerical methods, elasticity theory, statistical mechanics, and usually at least one course in one of the applied science departments. All students attend a weekly seminar arranged specially for the Graduate School in which they contribute themselves, and otherwise hear talks by members of the research group in mathematical physics and others. It has proved possible to arrange for each individual student a combination of courses which suits his particular interests and knowledge.

Although many of these courses are given for other purposes, students find it easy to synthesize their work and to build them into a common foundation of understanding.

The number of students in the course has remained small in the first three years, and is likely to continue small until the existence and purpose of the course become more widely known. It is therefore premature to give any statistics of the subsequent occupations of students who have obtained the diploma. These included work in industry and government laboratories as well as academic research. (One student took up postgraduate work in the Mathematical Physics Department at Birmingham, and two joined an applied science department in the University.)

The development of the Graduate School was greatly aided by the award of advanced course studentships of the Department of Scientific and Industrial Research, and in some cases by grants from the University of Birmingham.

R. E. PETERLS

WATER-RESOURCES AND WATER-USE SURVEY

THE study of the use and conservation of water resources is a relatively new geophysical science and one that impinges closely on other sciences such as meteorology and climatology, geology and geomorphology, agriculture, economic geography, demography, etc. The importance in the modern world of economic and land-use planning, particularly with reference to so precious a raw material as water, involves the collection of a vast and varied amount of data and information relevant to the assessment of water resources, on not only a national but also an international basis. Two papers*,

* World Meteorological Organization. Technical Note No. 25. Design of Hydrological Networks. Prepared by Max A. Kohler. Technical Note No. 26. Techniques for Surveying Surface-Water Resources. Prepared by Prof. Ray K. Linsley. Pp. v+16+vi+41. (WMO-No. 82 TP 32.) (Geneva: Secretariat of the World Health Organization, 1958.) 4 Swiss francs.

published by the World Meteorological Organization, are useful statements in this important field, particularly in view of the varying scientific standards of recording and observation that are available and possible in different world regions.

M. A. Kohler summarizes briefly the types of hydrological data, the network density of observations required, and network planning, and the techniques for estimating hydrological data that can be used. Attention is directed to the impracticability of devising a universally standardized procedure and a scheme is put forward for the creation of a minimum cover of permanent full, partial, and temporary observational stations.

The second, longer, technical paper is more closely concerned with techniques for the surveying of surface

water resources in a region, and providing estimates of usable water supply. Attention is given to methods which are adapted for use in the absence of adequate hydrological data and to simple techniques of observing hydrological phenomena which may provide useful data with least cost in time and money. Despite the importance of ground water circulation in all regions—and especially in arid regions—the survey is limited to the discussion of techniques with regard to surface resources. These are a guide to the estimation of requisite rates of replenishment of ground water that are necessary for the effective use of the latter over a period of time. The main topics discussed are the hydrological balance, precipitation, evapo-transpiration and its measurement, stream flow, sediment transport and water supply, and a summary direction for procedure in the matter of water resource surveys.

The special problems and peculiar needs of a densely populated and highly industrialized country such as Great Britain are summarized in an interesting discussion on a water use survey opened by Prof. W. G. V. Balchin (under the chairmanship of Prof. Dudley

Stamp), with contributions from experts representing a very wide range of technical interests in this important field (*Geog. J.*, 124, 476, 1958). Prof. Balchin directs attention to the dramatic increases in water consumption in Britain during the past century, culminating in an increase of 50 per cent in England and Wales and 41 per cent in Scotland during the short period 1938–50. The water storage capacity in the same time has increased by only 46 per cent and 31 per cent, respectively. The area where the consumption is greatest is the area where population is densest and the rainfall least, and where the local resources are already fully employed—that is, in lowland Britain and particularly in the great urban and industrial complexes.

These papers are a salutary reminder, through the many facets to the problem of water conservation that they reveal, of our ultimate dependence on water resources and our need to avoid over-exploitation of a raw material that in Great Britain at least, people assume all too readily is in abundant supply, and for which in many others the supply is already precarious.

ALICE GARNETT

CARNEGIE TRUST FOR THE UNIVERSITIES OF SCOTLAND

THE fifty-seventh annual report of the Executive Committee of the Carnegie Trust for the Universities of Scotland covers the year 1957–58 (pp. iv + 74, Edinburgh: Carnegie Trust for the Universities of Scotland, 1959) and includes the financial accounts for the year ended September 30, 1958. A major preoccupation of the Executive Committee during the year was the formulation of a policy to implement its new powers of investment. During the year there were on the books five senior research scholars, thirty-six research scholars in their second or third year, and twenty-five in their first year. For 1958–59 the value of the senior scholarship has been increased to £500 (with an additional £100 for expenses), while scholars at Oxford, Cambridge and London will receive £450, scholars living away from home, attending a Scottish or an English provincial university, £400, and scholars living at home and attending a Scottish university, £350. A grant of £4,000 a year for five years from the end of 1958 was made to the Scottish Dictionaries Joint Council subject to some conditions with regard to progress. Ten of the research grants awarded during the year were for expenses involved in illustrating the published results of research and five grants were made to authors as a subvention towards the cost of publishing their books.

Four grants are particularly mentioned. The Trust has provided a special heavy-duty vehicle and a 'Folboat' with outboard motor and a grant for running expenses to assist Prof. J. H. Burnett and Dr. D. H. N. Spence, of the University of St. Andrews, in preparing a comprehensive account of the aquatic vegetation of Scotland, a research which involves crossing many moorland roads to examine distant mountain lochs. A grant of £2,500 was made to Prof. R. H. Matthew, of the University of Edinburgh, for a study by a research team correlating the problems of the design of basic dwelling units, lay-out, siting and services

with social requirements, with specific reference to contrasting types of social grouping and including a cost study. Another grant was to the University of Glasgow North Rona Expedition, which spent about a month on North Rona and Sula Sgeir, paying particular attention to marine biology. Some very rare species of algae were found and a special census was made of Leach's petrel. A second successful expedition, assisted by a grant from the Trust, was one from the University of Aberdeen, led by Prof. A. C. O'Dell, to St. Ninian's Isle, Shetland, in June–July, 1958, in which a most important collection of silver ornaments was uncovered.

Of the ten grants for travel and maintenance made to members of university staffs engaged in research, three were to members of a faculty of medicine, four in science and three in arts. Among these may be mentioned those to Dr. W. I. Card to enable him to visit centres in the United States and Canada, where work of interest and importance in gastroenterology is proceeding, to Mr. Alastair Fraser to work in Copenhagen in the laboratories of Prof. M. Thomsen and Dr. F. Thomsen, leading authorities on insect endocrinology, and later in Liège, Brussels and Paris, to Dr. C. H. Gunningham to enable him to follow up in Scandinavia his investigations in Scottish heaths aimed at gaining a comprehensive picture of the ecology of heather, including its reactions to grazing and burning and influences of soil climate and at utilizing this information in an investigation of the ways in which heath lands have originated and are maintained, to Dr. Elizabeth D. Fraser, to enable her to test in America some of her hypotheses regarding perceptual constancy as a function of personality and learning and the effect of metabolic disturbance, and to Dr. P. H. Tait to discuss his experimental techniques in embryology in the United States.

THE SCHOOL HEALTH SERVICE IN BRITAIN

THE School Health Service is fifty years old. In the half-century of its existence there have been remarkable changes in the health of school children, and in the pattern of illnesses affecting them. Both boys and girls to-day are taller and heavier, better clad, better shod and cleaner. They reach physical maturity earlier and may expect to live twenty years longer. In sharp contrast to the conditions of malnutrition found only too commonly 50 years ago, medical attention is now being drawn towards an increasing number of school children who are too fat.

The annual report* of the Chief Medical Officer presents these facts and discloses among other vital statistics that the killing and crippling diseases prevalent at the turn of the century—tuberculosis, rickets and rheumatism—have been practically eliminated. The remaining causes of crippling and other forms of handicap are now mainly congenital or hereditary in origin. Accidents still kill twice as many children as die from disease, and road accidents are responsible for half the deaths recorded. Boys are more liable to death on the road than girls, leaving school in the afternoon is one of the most risky periods of the day.

Nearly 250,000 children were found to have verminous heads in 1957. This is about 4 per cent of the total school population. "This condition is preventable and there is seldom any excuse for it", says the report. "It is essentially a family problem, children being infested and re-infested by adults". The current question of smoking and its relation to lung cancer provides "a striking example of the need

* *The Health of the School Child. Fifty Years of the School Health Service* (Report of the Chief Medical Officer of the Ministry of Education for the years 1956 and 1957). Pp. 1+220+12 plates (London: H.M. Stationery Office, 1958) 10s. 6d. net.

for boys and girls, while still at school, to be taught something about healthy living—by example, perhaps, more than by precept. In spite of all that has been said and written about the close connexion between the two, many children still smoke cigarettes". A recent inquiry carried out at a mixed secondary modern school in the Isle of Wight disclosed that about a third of the boys and 15 per cent of the girls were regular smokers.

The incidence of dental decay has increased in the past few years among school children, and is due "probably to the greater amount of sweets and confectionery eaten since the end of sweet rationing". Fluoridation of water supplies probably offers the best hope of reducing this incidence, "but large scale benefits from this measure can hardly be expected for several years".

One consequence of the changing pattern of ill-health in childhood is that school health service staffs now devote more attention to children who are emotionally disturbed, or who suffer from some handicap which threatens to have a retarding effect on school progress from a psychological cause.

There is also the challenge of the delinquent school child which cannot be ignored by the school health service. The number of children charged before the juvenile courts has risen from 13,000 in 1913 to 38,000 in 1956. It is right, says the report, that the school health service should concern itself with the problem and co-operate with the other agencies involved. In 1957 more than six and a half million children attending about 30,000 maintained and assisted schools were covered by the service. More than two million have a periodical inspection during the year.

INCENTIVES IN THE BUILDING INDUSTRY

A RECENT Building Research Station report* on incentives in the building industry shows that bonus schemes have an important contribution to make to building efficiency. The maximum benefit can only be derived, however, if they are integrated into a rational pattern of management. The report enumerates principles on which an incentive scheme should be based as well as the method of operation if it is to be successful.

Operation targets, coupled with a recording system giving operation costs, should be used whenever possible. The operations should be the visual stages of work, of about one week's duration, and continuous jobs with no hold-ups for other trades.

The scheme should be designed to suit individual needs and local conditions. This calls for flexibility in targets to suit the local productivity of labour and

the distribution of bonus payments. The operatives on each site should decide the method of sharing within the bonus group or gang. It is necessary to safeguard the quality of work by making site staff independent of production bonus and improving site supervision of quality.

A number of conclusions were reached about the methods of operation of an incentive scheme. Accurate and well-balanced targets should be maintained by the systematic use of cost information from all the firm's sites and by close consultation with its site staff. The incentive effect of a scheme is greatest when it is given a central position in the organization of the firm, especially if administered by the contract management side. There should be close liaison between estimating and the fixing of target bonus-rates. The principles of the scheme should be kept simple and explained to the operatives so that they can calculate their own bonuses. The bonus units are small gangs.

* *Department of Scientific and Industrial Research. Building Research Station. National Building Studies Special Report No. 28. Incentives in the Building Industry*. By Allison Entwistle and W. J. Reiners. Pp. iv+43 (London: H.M. Stationery Office, 1958) 3s. net.

The bonus paid should be the actual amount of bonus earned, there should be no limit to the amount of bonus that can be earned, the bonus should be paid weekly and as soon as possible after the completion of the operation. The scheme should cover, so far as possible all the work on the site. Good labour relations on the site are an aid to productivity

and should be encouraged by presenting the targets to the operatives for agreement before work starts and a recognized channel for complaint should be established. Provision should be made to allow targets to be modified on a particular site if adequate reason is established. Disputes or complaints should be dealt with speedily and in consultation with the site staff

SURFACE OF THE OCEAN AS A SOURCE OF AIR-BORNE NITROGENOUS MATERIAL AND OTHER PLANT NUTRIENTS

By DR. A. T. WILSON

Division of Nuclear Sciences, Department of Scientific and Industrial Research
Lower Hutt, New Zealand

IN an earlier communication¹ the occurrence of organic nitrogen in New Zealand snows was reported, and it was suggested that this might represent a contribution to the nitrogen economy of New Zealand soils. This article presents further results on the subject and points to the most probable origin of this air-borne nitrogenous material.

Samples of snow have been collected from above the vegetation line to avoid possibility of contamination by plant or animal debris. This was done in preference to the more conventional rain water sampling which is open to large contamination errors. The analyses of these samples are shown in Table 1.

Since the samples described here were freshly collected snow from regions where no plants or animals exist, contamination from these sources should be negligible. No insoluble inorganic material was visible in the samples, so that cyclic terrestrial dust could not contribute appreciably to the nitrogen found in the samples. This is to some extent further supported by the lack of nitrate in the samples. The samples were collected in early and mid winter when the pollen contribution would be negligible. It seems that precipitation, at least in New Zealand, does in fact contain appreciable quantities of bound nitrogen which does not arise from contamination

and, if heavier, sinks to form sediments, and if lighter, rises to form this layer, which therefore contains micro-organisms and other plant-life in a state of partial decomposition and would be expected to be rich in organic matter. It would also be expected to have an increased potassium/sodium ratio, since many marine organisms concentrate potassium. It is known² that when a bubble of gas passes through a liquid gas interface the act of the bubble bursting throws up a small droplet from the surface of the liquid into the gas phase. This must occur in the phenomenon known as 'white caps' (that is, when a wave breaks). The haze produced by these particles is quite noticeable on a fine day when a heavy surf is running. Thus the composition of these droplets reflects that of the surface layer and not that of the bulk ocean.

It is reasonable to assume from the foam produced in rough ocean that some surface active material is present on the surface of the ocean. During strong onshore winds large quantities of foam accumulate on the shores of New Zealand which provides an opportunity to sample directly the surface layer of the ocean. A sample of ocean foam was collected on the west coast just north of Wellington. The foam was broken with a silicone anti-foaming agent and allowed to stand. It proved to be 25 per cent solid matter. On microscopic examination this material was found to be particularly rich in bacteria and also had large quantities of diatoms and fragments of phyto and zoo plankton. The chemical analysis of this material is shown in Table 1. It is interesting to note the high nitrogen content and that the potassium/sodium ratio is higher than that in sea water.

The relationship between the surface layer of the ocean and snow water is most clearly seen when one plots the excess potassium concentration against the 'albuminoid nitrogen concentration'. This is done in Fig. 1. The excess potassium concentration is obtained by subtracting from the potassium concentration 1/27 of the sodium concentration, that is, that amount of potassium which would be associated with the sodium in sea water. We see that the results from the ocean foam and the snow water samples lie on a straight line which can be extrapolated back to give the albuminoid nitrogen concentration in sea water. This is strong evidence in favour of a common origin and supports the

Origin of Organic Nitrogen in Snow

The problem immediately arises as to the origin of this material. When one considers the geographical position of New Zealand, situated as it is in a westerly air stream and surrounded by thousands of miles of ocean it is difficult to avoid the conclusion that the source is the ocean itself. The ocean however contains only about 0.003 ppm of albuminoid nitrogen. Further, if the snow is analysed in more detail, one sees that it is not merely diluted sea water but that its potassium/sodium ratio is an order of magnitude greater than that of sea water.

In order to explain these facts, it is necessary to postulate that the upper very thin layer of the ocean has a different composition from that of the rest of the ocean. In particular that it is enriched in potassium ammonium organic material and organic nitrogen and probably various other materials. It is suggested that most (for example, from plankton) is other than sea water

Fig 1

nitrogen in snow originates in the surface layer of the ocean

The above evidence suggests a new path in the nitrogen cycle, at least for New Zealand, and probably for other areas with rough oceans to their windward. Elementary nitrogen dissolves in the sea and is fixed by marine micro organisms. These eventually rise to the surface and are caught in the surface layer, where some are partly decomposed by other micro organisms into ammonia and other products. The micro-organisms and their decomposition products are carried into the air by a bursting air bubble in a 'white cap'. In the air the droplet would lose its moisture and a part of its ammonia, and as a small and light particle be carried far inland to settle out or to serve the very useful function of seeding rain clouds. On reaching the ground this material would contribute to the soil, nitrogen and potassium and possibly other materials necessary for plant growth. From the lack of NO_2 and NO_3 in the samples, this path in the nitrogen cycle might be considered more important than the conventional fixation of atmosphere nitrogen by atmospheric electrical discharges, at least for the areas covered by the sampling. This then might represent a net transfer of bound nitrogen from the ocean to the land.

Table 1

| Description of sample | Nitrogen content of snow samples (ref 3) | | | | | Na^+ (p p m) | K^+ (p p m) | Corrected $\text{K}^+ = \text{K}^+ - \frac{1}{27} \text{Na}^+$ (p p m) | K^+/Na^+ |

Application of Hypothesis to Other Problems

Origin of Ammonia in Air and Rain The presence of ammonia in air and rain has been known for many years. Its origin, however, has been in doubt.¹ The ocean seemed to be the most likely source except that calculations based on the equilibrium constant between air and water, together with the concentration of ammonia in the sea, rule out this possibility, even though in New Zealand's case there seems to be no other. The hypothesis presented in this article would imply that the ammonia is coming, not from the bulk ocean, but from the surface layer and from the evaporation of the small droplets which are thrown up into the air by the bursting bubbles. Variable quantities of ammonia will be lost by these droplets to the air, depending on their pH and composition. Indeed, the results in Table 1 seem to show that the higher the albuminoid fraction the lower the ammonia retained in the droplet and vice versa. This might be due to the buffering effect of the basic nitrogenous material.

Potassium/sodium ratio in rain water It is a well known fact that the potassium/sodium ratio in rain water is often larger by a factor of 10 than that in the sea—the obvious source. This can be readily explained in terms of the above hypothesis, since the rain would derive its salts from the surface layer of the ocean, which in turn is rich in marine organisms many of which are known to have much higher potassium/sodium ratios than the 1/27 of sea water.

Charge discrepancy in rain water The total sums of all the charges carried by the anions and cations in rain water sometimes do not balance. This can be explained by the presence of organic compounds balancing the excess charge.

Ocean foam The origin of the foaming agent in the sea is not certain, but it is possible that it is produced

by the bacteria themselves and serves to trap their food and also to aid in their aeration.

Many of the sheep stations on the New Zealand coasts and islands carry more sheep than might from other considerations be expected, and without aerial top dressing.² This effect decreases with distance from the sea, and applies only to areas lying within 10 miles of the coast. Could this be the result of wind blown foam carrying plant nutrients to these coastal areas?

Bacterial action of the sea There is a discrepancy between the supposed bacterial action in the sea and the very few bacteria found therein.³ Is it possible that a large fraction of these biological processes takes place on the surface layer of the ocean, and that these are not effectively sampled by the normal methods which sample the bulk ocean rather than the surface?

Life in the inter tidal zone The occurrence of large quantities of organic matter and nutrients in the surface layer of the sea might provide the food supply for the large amount of life that exists in and near the inter tidal zone.

I wish to thank Mr H. J. Wood of the Dominion Laboratory, Wellington, for the nitrogen analyses, and Mr A. J. Heyne and Mr G. Pallo Department of Scientific and Industrial Research, for collecting samples.

COMBINED EFFECTS OF CORTISONE AND INSULIN ON DEVELOPING CHICKEN EMBRYOS

By DR. PIETRO de FRANCISCIS* and PROF. WALTER LANDAUER
University of Connecticut

THE injection of insulin into the yolk sac of chicken eggs after an incubation period of 4-8 days is responsible for the occurrence of a shortening of the long bones of the legs (micromelia) and of abnormalities of the beak, the mean body weight of such embryos is somewhat reduced. The severity of these symptoms varies with the amount of injected insulin.¹ The principal effect of cortisone, injected during the same developmental stages is a marked dwarfing of the embryos, but without the production of skeletal malformations.² When both insulin and a potent adrenal cortex extract (but of unknown cortisone concentration) were injected after 5 days of incubation it was found that the incidence of insulin specific skeletal abnormalities was significantly greater than after the injection of insulin alone.³ In similar experiments but done after 8 days of incubation and using cortisone in combination with insulin, Lunardo and de Bastiani did not find a potentiation of the insulin effect.⁴ It seemed of interest therefore, to determine if differences of developmental stages

are responsible for dissimilarities in the effects produced by simultaneous treatment with cortisone and insulin or if the discrepancies between our earlier observations and those of Lunardo and de Bastiani have other causes.

For our present tests we used eggs of White Leghorn fowls. Sterile solutions of cortisone (cortisone acetate, Merck) and of insulin (Lilly) were injected into the yolk sac after 4 or 8 days incubation. The details of our experiments are presented in Tables 1 and 2. In recording skeletal abnormalities all degrees of shortening of the legs were pooled similarly, all types of beak defects were grouped together. The incidence of other skeletal abnormalities was very small and was not separately recorded, these defects occurred with about equal frequency in all groups and, since there was no reason for believing that they owed their origin to our experimental procedures, they were added to the 'normal' groups.

Untreated eggs served as controls of the various experimental groups. For the test reported in Table 1 we had 37 fertile and untreated eggs; 33 of these

* Fellow of the Italian

Council.

Table 1 EXPERIMENTS IN WHICH CORTISONE, INSULIN, OR BOTH CORTISONE AND INSULIN WERE INJECTED INTO THE YOLK SAC OF WHITE LEGHORN EGGS AFTER 96 HR OF INCUBATION AND AT THE DOSAGES GIVEN BELOW

In those groups in which both hormones were injected the ratio of cortisone to insulin amounted to 0.47 in experiments 1 and 2, and to 0.25 in experiment 3. All living embryos were weighed and examined after 18 days of incubation. Incidence of 'normal' embryos and of abnormalities of the legs or beak in percentage of survivors to eighteenth day. Standard errors of body weight.

(89.2 per cent) survived to 18 days and the embryos at that age had a mean body-weight of 20.95 ± 0.53 gm. As controls for the experiments of Table 2 we had 26 fertile and untreated eggs, 22 of the embryos (84.6 per cent) lived at 18 days and had a mean weight of 19.37 ± 0.56 gm. None of these 55 embryos showed skeletal malformations of the kind with which the present discussion is concerned.

Effects on survival. Among embryos treated at 4 days with both insulin and cortisone the mortality was consistently higher than it was in the groups treated with either hormone alone. In fact, the toxicities of insulin and cortisone were nearly additive, and most of the group differences in mortality (or survival) are highly significant. At 8 days, on the other hand, survival after the combined treatment did not differ significantly from that occurring after injection of either insulin or cortisone. Comparing the experiments at 4 and 8 days, and taking into account such dissimilarities of dosage as existed, no consistent or significant changes appear to have occurred in the toxicity of either cortisone or insulin. Highly significant differences are found, however, between the combined treatments at the two developmental stages. In experiments 1 and 2, in which the ratio of cortisone to insulin was higher at 8 days than at 4 days (0.47 vs 0.39), the differences amounted to 31.4 ± 8.65 and 39.7 ± 8.90 per cent respectively, in the two third groups, with identical ratios (0.25), the difference in survival was 38.2 ± 7.04 per cent.

Effects on body-weight. Following treatment after 4 days of incubation, the injection of both hormones led in all three groups to a greater retardation of growth than that produced by either insulin or cortisone. In groups 2 and 3, the mean body-weights, after combined treatment, fell significantly below those of the groups treated with either cortisone or insulin alone. At 8 days the combined treatment

led to a significantly lower body-weight in comparison with the insulin-treated embryos, but the differences between the groups that had been injected with both hormones and those that had received only injections of cortisone were neither consistent nor statistically significant. A comparison of the treatments at the two developmental stages reveals some interesting differences. Against the lowest amount of cortisone which we used (1 mgm/egg) the 8-day embryos had become significantly more resistant than those treated at 4 days, their mean body-weight being 2.66 ± 0.94 gm higher, the results of experiments 1 and 2 are not directly comparable because of dosage differences. The injection of 3.2 units of insulin at 4 and 8 days did not produce significant dissimilarities in body-weight, but after 4 units the 8-day embryos were less retarded (difference 4.38 ± 0.88 gm). The results for combined injection of insulin and cortisone in experiments 1 and 2, because of dosage differences, do not allow a comparison between 4 and 8 days, but the results of tests with 1 mgm cortisone and 4 units insulin (experiments 3) demonstrate that growth of the embryos treated at 8 days was much less retarded than it was following injection at 4 days (difference 4.71 ± 0.27 gm).

Teratogenic effects. As one would expect, the incidence of malformations increased with dosage in the groups treated with insulin alone and in those treated with insulin and cortisone. This was true at both developmental stages. A comparison of the effects of insulin treatment with the results of the combined injection of insulin and cortisone shows no significant differences in the incidence of skeletal defects at the 4-day stage, except for a slight but consistent trend of the abnormalities to be more extreme in the groups treated with both hormones, in the groups tested at 8 days, on the other hand, the combined treatment was less teratogenic than injection of insulin alone. For the pooled data of experiments 1 and 2 (with identical ratios of cortisone

to insulin) these differences were highly significant ($\chi^2 = 16.82$, $P < 0.001$), and the same is true for the combination of probabilities for experiments 1, 2 and 3 ($\chi^2 = 30.31$, $df = 6$, $P < 0.001$).

Our results demonstrate clearly that between 4 and 8 days of incubation a change occurs in the reactions of the developing chicken embryo to combined treatment with insulin and cortisone. The older embryos survive better, show less retardation of growth and a lower incidence of skeletal malformations. These differences in response presumably are a reflexion of the homeostatic forces which the incipient functioning of the endocrine systems brings into play. Our observations, secondly, confirm the

report by Lunardo and de Bastiani that cortisone does not potentiate the teratogenic action of insulin. Since our earlier experiments with an extract of adrenal cortex produced very striking potentiation, it must be concluded that this was due not to 17-hydroxy 11-dehydrocorticosterone (cortisone) but to one or more of the other corticosteroids contained in the extract. This we hope to verify in future experiments.

MATERNAL CONTROL OF OVARIOLE NUMBER IN THE PROGENY OF THE MIGRATORY LOCUST

By F. O. ALBRECHT

Laboratoire d'Evolution des Etres Organisés Paris

M. VERDIER

Laboratoire de Biologie Animale, Paris

AND

R. E. BLACKITH

Imperial College Field Station, Sunninghill, Berks

AN integral part of the phase theory of locust transformations is the cumulative transmission of phase characters from one generation to another, so that fully *gregaria* or *solutaria* types can be obtained only when crowding or isolation of the locusts is maintained for several generations. The transmission of phase status to the progeny is held to occur through the accumulation of extra-chromosomal materials in the egg.¹ Early criticisms, understandably in view of the specific status given to the phases previously, held that they were genetically distinct but formed hybrids.

The weight of field and laboratory evidence has now accumulated to the point where the essentially non-genetic nature of this inheritance is taken for granted, although the capacity of expressing it depends patently on the genotype concerned. This striking illustration of what Thoday² has called phenotypic flexibility has received scant notice save for some remarks of Kennedy.^{3,4}

Hunter-Jones⁵ has shown that crowded female desert locusts reproducing parthenogenetically, produce offspring which in colour and weight are typically *gregaria* whereas the same stock of females when isolated, give *solutaria* type larvae. Our experiments show that talotikus parthenogenesis also occurs with the migratory locust, *Locusta migratoria migratoria* R. and F.⁶ Moreover, the number of ovariols in female offspring of isolated unfertilized females ranges from 95 to 105, whereas hatchlings from crowded mothers carry only 75-85 ovariols. We may look to the female reproductive system for some of the clues to this problem.

There seem, in fact to be two physiological processes at work, one of these operates through the vitellus of the egg, the reduction of which by ligaturing after blastokinesis produces larvae which have the *solutaria* coloration (pale green) from crowded stocks of the migratory locust, the normal larvae of which

would be black and heavy.⁶ Generally, weight and colour are closely associated,⁷ both with one another and with the subsequent rate of development and number of moults of some species of locust.⁸ The number of ovariols borne by these ligatured larvae is, on the contrary, typical of *gregaria* populations. Thus the inheritance of this important phase character⁹ seems to be independent of the amount of vitellus remaining in the egg. This distinction, however, may prove to be one of the timing of the processes of ovari formation and larval coloration; in *Melanoplus* and *Drosophila* at least, ovariole number seems to be determined prior to or during blastokinesis.^{10,11}

Table 1. MEAN REGRESSIONS OF OVARIOLE NUMBER ON HATCHLING WEIGHT OF THE MIGRATORY LOCUST REPRESENTING THE INCREASE OF POTENTIAL REPRODUCTIVE CAPACITY FOR A SACRIFICE OF 1 MM WEIGHT AT BIRTH.

| Generation | Regression and subsequent rearing density |
|------------|---|
| I | Crowded (Stock from Musée d'Histoire Naturelle Paris) |
| II | Crowded |
| III | Crowded |
| IV | Crowded |
| V | Crowded 1.27 Isolated 2.85 |
| VI | Crowded 1.90 Isolated 1.75 |
| VII | Crowded 1.27 Isolated 0.93 |

There is in general an inverse relation between weight at hatching and the number of ovariols in locust larvae.¹² The interlocking of these two characters depends on the consistency with which the earlier generations have been kept crowded or isolated. To the extent that we may think of this relationship as a measure of the interchangeability

of reproductive potential (number of ovarioles) and larval mobility (weight of occluded food reserves) the changes of its magnitude are of interest whatever the mechanism of inheritance. Table 1 shows the mean regressions of ovariole number on hatching weight for comparisons made among larvae issuing from one and the same egg-pod. Each pod contains up to 100 eggs derived from a single ovarian cycle in the female. Comparisons across egg-pods or across the progeny from different females are swamped by extraneous sources of variation which themselves depend on the consistency of ancestral density. Generation VI (crowded grand-parents, isolated parents) were 67 times as variable as generation VII, for which isolation was the parental and grandparental regime. Yet even generation VII was 9 times as variable, as a whole, than were contrasts made within egg-pods as are those in Table 1. These varied in precision scarcely at all throughout the experiment.

Crowding leads to a cumulative gain in weight at hatching for a given sacrifice of reproductive potential, and since this sacrifice has evidently not entirely been made good even three generations after crowding was ended we have the longest reach, of any yet recorded, of a density-dependent effect being transmitted to the descendants of the crowded generation. Similar inheritance has, however, been demonstrated in the shorter run with other characters^{6,7}. In a general and less-precise way this inverse relation may be extended to fully *solitaria* and *gregaria* females, the progeny of the *gregaria* are fower and heavier, and have fewer ovarioles compared with the progeny of *solitaria*, nevertheless, both phases produce about 1 gm of living material in each egg-pod.

Setting Limits to Selective Action during the Egg Stage

Our series of 6,000 preparations of the dissected ovaries of several generations of the migratory locust affords an opportunity to set limits to the action of any selective forces operating during the development of the eggs, for the number of ovarioles in the laying female is the upper limit to the number of her progeny from which the issue of any one egg-pod can have been selected, always excluding the possibility of pre-ovogenetic selection. In particular, the sequence of egg-pods laid by isolated females was studied either when the female was left with the male after copulation for the rest of her life, when the number of ovarioles in her progeny steadily diminished, or when the male was removed after 24 hr in the cage, to allow copulation to occur, when no such diminution was observed. The influence of the male, once fertilization has been accomplished, is mildly to disturb the female and to induce a modest amount of those inhibitory effects normally associated with crowding. The mean ovariole number of offspring from a female left with one male drops by one ovariole for each of the 15 or so reproductive cycles that the female undergoes. More drastic crowding augments this progressive loss but also shortens the sequence of reproductive cycles so that the net effect is not greatly different.

'Crowding' the females with a single male produces offspring of which the mean number of ovarioles eventually lies outside the range of the phenotypes initially produced by the same mating pair. At most, less than half this cumulative shift can be attributed to selection, and in fact there is no evidence that any of it is so induced. The absence of such a

shift, in females from whom the male is removed within a few hours of copulation, excludes any influence of age alone on the mother.

Regulation of Fertility and Fecundity in the Migratory Locust

Implicit in the phase theory of locust outbreaks is some autoregulation of fertility or fecundity according to the population density. Our results provide some idea of the nature of such regulation in the migratory locust, other species seem to differ in important respects, and caution is needed in extending these findings to them.

The influence of crowding operates both within and between generations. The distinction between larval and adult crowding is vital for these comparisons, since changes of density rather than the level of the density seem to elicit the regulatory processes. Crowding during the larval instars almost doubles the number of egg-pods laid by the ensuing adult females, whereas adult crowding inhibits the laying female either from fulfilling her potential delivery of egg-pods or from endowing her female offspring with their appropriate complement of ovarioles. In this way larval and adult crowding act in opposite directions, and may substantially nullify one another during consistent crowding. Yet when the larvae are crowded and the adults isolated, as occurs with stragglers from gregarious groups, as many as 1,500 eggs may be laid by each female, when the reverse regime is imposed, only about a tenth of this number is to be expected.

However clearly one may recognize that these ideas relate only to a few aspects of a much wider problem, the control of fecundity in the migratory locust may be regarded as a homeostatic mechanism tending to stabilize population density. In every generation we have found a significant negative regression of ovariole number on hatching weight, which we interpret as a latent ability to exchange larval food reserves for reproductive capacity. When grouped locusts are dispersed, this adjustment is called into play and only fades away when several generations of isolation have failed to restore the population density through an increase in fecundity of the offspring. The last word in these matters often lies with the climate, which can override the locusts' best endeavours at regulation¹³.

Generally, it appears that the ability to produce offspring, the average fecundity of which is well outside the phenotypic range of the parents, lies at the heart of the capacity of migratory locusts to cope with rapidly changing environments. An analysis of growth and of moulting polymorphism in the red and desert locusts led us to conclusions in the same vein⁸. A full account of the experiments on which the present conclusions are based is being published⁹.

PHYSIOLOGY

An Exteroceptive Block to Pregnancy in the Mouse

EXPERIMENTS on the effect of certain oral progestogens during early pregnancy, in continuation of previous observations¹ on non pregnant animals involved placing a recently mated female receiving oral progestogen with a strange male. In a number of the mice the procedure resulted in failure of pregnancy from the first mating and a new mating within 3-6 days. Control experiments showed that the same effect was produced by dosage with inert material or even without any treatment other than the introduction of a strange male at 24 hr after mating. 20 out of 40 females behaved in this way a far greater proportion than could be attributed to the expected incidence of anovular cycles. Only about 8 per cent of young females, as used, return to oestrus within 4-5 days if removed from the male after their first mating, or copulate again at this time if they are left with the male. Moreover, among the suspect females there was a failure of the pseudo-pregnancy which might have been due to poor stud males. Experiments were therefore undertaken to explore this effect.

Two test situations were devised. Situation A was as already mentioned that is, the recently mated female was paired with a strange partner 24 hr after copulation with the stud male. Situation B was one of proximity without contact, the female being housed in a small cage inside a stock box containing other mice which could climb about the cage but not enter it.

The stud males and all the females were albinos. The test males were either albino or wild type. Young virgin females were mated in pairs with a stud male, the females were removed from the male when the vaginal plug was found and housed together overnight. 24 hr later they were presented with the test situation. The females were generally left in the test situation for 7-10 days, and they were then removed to normal mouse boxes. The pregnant females were isolated before parturition, and females which became pseudopregnant or in which the pregnancy had been blocked received a fertility test with a stud male. The few females which proved to be infertile were excluded. Daily vaginal smears were examined.

The results of these investigations are briefly summarized in Table I.

Pregnancy was blocked and implantation inhibited in nearly 30 per cent of females by the introduction of a strange male within 24 hr of coitus. It was so blocked even by the presence of a castrated male. Pregnancy was not affected by the return of the female to her original stud male or by the presence of a strange female, whether parous or ovariectomized. Contact between the sexes was not necessary for this effect. Pregnancy was also blocked when the female was caged inside the male stock box. Among parous females, pregnancy was less readily blocked than among non parous by contact with a strange male

Table 1. PREGNANCY BLOCK IN THE MOUSE. The females were separated from stud males on finding vaginal plug and housed together until presented with the test situation 24 hr later.

| Test situation | Females having blocked pregnancies | |
|---|---|----------|
| | Proportion | Per cent |
| A Housed with | | |
| | Strange normal male (albino) | 10/69 28 |
| | Strange wild type male | 26/35 71 |
| | Castrated male (albino) | 13/50 26 |
| | Another female (parous or ovariectomized) | 0/48 — |
| B Proximity without contact that is in cage inside stock box containing | Original stud male | 0/32 — |
| | Albino males | 8/32 25 |
| | Wild type males | 52/68 76 |
| | Females | 0/49 — |

but apparently broke down as easily when the female was housed inside the male stock box. This suggests that the latter situation supplies a stronger stimulus.

In both test situations the superiority of the wild type males over the albinos as pregnancy blocking agents was highly significant. The reason for this difference is not understood and as yet male mice of other strains have not been tried. Two different strains of females, one albino and the other pink-eyed champagne, were tested in small numbers in situation B. Both exhibited pregnancy block in similar proportions to those found for the original mice.

The use of the genetically marked wild type test males showed that superfecundation did not occur. Of 35 females 15 mated with the test male. All 15 gave birth to black-eyed young only (123 young). This includes one female in which coitus with the test male took place within a few hours of introduction her litter of 8 black-eyed young being born 10 days later, 20 days after finding the vaginal plug from the stud albino male.

No mutual reaction between females as regards pregnancy block was indicated either when the test situation involved other females or when the mated females were themselves placed singly in pairs or in threes in the test situation. It is well established, however, that females exert a powerful effect upon one another in terms of the oestrous cycle² and the incidence of mammary cancer³ and that the presence of a male tends to synchronize the cycle of non-pregnant females⁴.

Further experiments designed to throw light on the mechanism involved in this pregnancy block of exteroceptive origin are in progress. The pituitary and the hypothalamus are probably both implicated.

Retinal Responses of Pink Salmon associated with its Downstream Migration

THE seaward migration of juvenile Pacific salmon is usually nocturnal and confined to a relatively brief portion of the night¹. It has been suggested that "as the light intensity falls rheotactic responses, which are to a large degree dependent on vision, fail, and these fish pass down stream in shoals. The fact that such mass movements occur during a rather precise period of the night is probably due to the dark adaptation of the eye and a period of night blindness"². In support of this view, a recent histophysiological examination of the retinae from several species of *Oncorhynchus* has shown an incompletely dark-adapted condition of the retinae at the time of most active downstream migration^{3,4}. As a further test of this hypothesis, the retinae from fish killed at different light intensities during the evening and early morning have been compared with the retinae from fish which were completely adapted to the same light intensities in the laboratory. The pink salmon fry (*Oncorhynchus gorbuscha*), probably the most specialized of the downstream migrant salmon¹, was selected for the study.

Migrant pink salmon were collected from a trap in Jones Creek, British Columbia, and brought into a dark room of the laboratory. Groups of five fish were exposed for 90 min to each of seven light intensities, ranging evenly from 10^2 to 10^{-4} ft-candle. The period of exposure was sufficient to bring about a complete adaptation^{3,4}. Fish captured in the same place and in like manner were placed in glass aquaria which were located in an exposed position in the river where the fish had been migrating. The bottoms of the aquaria were covered with sand and gravel. From these aquaria, fish were sampled at seven times when the incident light intensity reached the same values used in the laboratory. This was done both at twilight and at dawn. Light intensities of 10^{-1} ft-candle and greater were measured with 'Photovolt' model 200 photometer and light intensities below this value with 'Photovolt' model 520-M electronic photometer.

The eyes of teleost fish adapt themselves to altered light conditions by pronounced changes in the distribution of the retinal epithelial pigment and the position of the rods and cones. When the light intensity falls below threshold values, the retinal pigment concentrates and the rods and cones migrate due to the contraction and expansion, respectively, of their myoids. These movements are in direct proportion to the logarithm of the light intensity. Thus in bright light, the rods are shielded by the pigment and the cones placed directly in the path of light, whereas in low light intensities and darkness, the rods are brought directly in the path of light and the cones migrate closer to the concentrated pigment. These processes can be followed by measuring the thickness of the pigment and cone layers. The cones are more obviously delimited for this purpose than the rods. The histological techniques and methods of measuring retinal changes have been described^{3,4}. The values presented here are means for 50 measurements made from 10 eyes in each case.

Fig. 1 shows that both pigment and cone layers of pink salmon retina are in a semi-adapted state when the light intensity is rapidly changing in the morning. The

Fig. 1 Thicknesses of the pigment and cone layers of pink salmon retina when fully adapted to a series of light intensities in the laboratory and at the same intensities under conditions of rapidly changing morning and evening light in the field.

picture and the semi-adapted state in Nature is less at dawn than in the evening. This is in accord with an earlier demonstration that light adaptation is more rapid than dark adaptation in this species⁴. Under natural conditions, in the evening, both pigment and cones are in a fully adapted state at intensities above 1 ft-candle. However, between this level (the cone threshold) and 10^{-3} ft-candle the retinae of animals fixed in the field are not as completely adapted as those in the laboratory. At 10^{-4} ft-candle adaptation is the same in both groups. It requires about 45 min (Fig. 1) for the light intensity to fall from 1 to 10^{-4} ft-candle. Ali⁴ has shown that retinal adaptation commences below 1 ft-candle and requires about 45 min to reach a maximum. Thus, the changes in the field are in accord with the laboratory findings. With increasing light, retinal changes are evident at intensities above 10^{-2} ft-candle and adaptation is essentially complete at 1 ft-candle. The rapidity of light adaptation⁴ would seem to account for the small differences found in the fish sampled at dawn. Actually, the changes in light intensity in Nature are somewhat more rapid at dawn than at dusk (Fig. 1).

These findings are in accord with the theory that migration of pink salmon is initiated when the retina is only partially adapted to the decreasing illumination. At Jones Creek, where these observations were made, it was found that 80 per cent of the pink migrants entered the trap between 7 p.m. and 9 p.m. (Pacific standard time) on the nights of the study.

During this period the light intensity decreased below 1 ft candle and reached 10^{-4} ft-candle. It is not to be expected that all the fish will be affected at the same time since there are shaded and exposed areas in every stream. These observations, however, support well the theory that, whether the pink salmon is transported or actively swims downstream¹, its nocturnal movement will be initiated when visual contact with its environment is reduced or impaired. This will be associated with the rather specialized behaviour of rising to the surface of the water at low light intensities¹.

Deoxyribonucleic Acid Formation in Multiplying HeLa Cells

WHILE studying the behaviour of parasyn-
chronously dividing HeLa cells (Gey), Newton and
Wildy¹ have measured the amount of deoxyribo-
nucleic acid as a function of the time interval between
one division and the next. Their results suggest that
the synthesis of deoxyribonucleic acid occurs during
two periods in interphase: one soon after and one
just before cell division. Between these periods in
mid interphase, there exists an interval during which
the amount of deoxyribonucleic acid (DNA) in the
cell remains approximately constant (Fig 1, curve a).

Partial confirmation of this result, using a micro-
spectrophotometric technique, has been obtained in a
further series of experiments made with randomly
dividing cultures. Replicate cultures of HeLa cells
were grown on cover glasses held in 10 ml hard glass
screw capped bottles. These were made by intro-
ducing into each bottle 1.0 ml Gey's saline containing
30 per cent human serum 0.5 per cent lactalbumin
hydrolysate (Nutritional Biochemicals Inc.), 100
units/ml penicillin, 100 mgm/ml streptomycin and
0.003 per cent phenol red in which were suspended
250,000 separated cells. After incubating at 37° C

Fig 1

Fig 2

for 36 hr the cultures were fixed in methanol, stained by the Foulgen technique and the amount of chromophore per cell was measured for 70 cells (from two different cultures) by the two wave length technique², using the microspectrophotometer made by M L Mendelsohn³ in the Department of Radiotherapeutics, Cambridge. From these measurements a histogram has been constructed which shows the distribution of the chromophore, and hence the relative amounts of deoxyribonucleic acid, among the individual cells of the culture (Fig 2).

Walker⁴ has shown how the synthesis curve for deoxyribonucleic acid max, with certain restrictions, be constructed from such a histogram. It is believed that the cultures used for the estimation satisfied these conditions. Fig 1, curve b, has therefore been constructed from the histogram of Fig 2.

Comparing the curves in Fig 1, it will be seen that whereas it is not possible to tell from Fig 1b whether the early formation of deoxyribonucleic acid shown in Fig 1 curve a, occurs, there is certainly a rapid synthesis beginning about 5 hr before cell division and continuing up to a comparatively short time before cell division.

The late period of formation of deoxyribonucleic acid agrees with the findings of Walker and Yates⁵ using other kinds of cells and with those of Painter and Drew⁶ using tritiated thymidine on cultures of growing HeLa cells.

It is, however, difficult to explain the failure to detect the earlier rise in deoxyribonucleic acid which was found with parasynchronously dividing cultures though the following two explanations should be considered: (1) that the present method is inadequate for demonstrating such a rise, (2) that the early rise is characteristic only of parasynchronously dividing cells. The latter explanation is thought to be more likely because in such cultures the early rise in deoxyribonucleic acid has never been observed before the first cell division has occurred.

A limit to the end of the synthesis period has been obtained by examining autoradiographs of cultures growing in the presence of tritiated thymidine. After 36 hr growth, tritiated thymidine (Schwarz 3.0 c/mM) was added to the medium to give a concentration of 1 μ c/ml and 30 min later, the culture was fixed in methanol. The cells were afterwards stained with galloxyanin and autoradiographs were prepared. In these although interphase cells were well labelled examination of several hundred cells in all stages of mitosis showed that none of them was labelled. From this it can be deduced that synthesis of deoxyribonucleic acid ends at least 1-1½ hr before the commencement of mitosis, since

the cells were in the thymidine for $\frac{1}{2}$ hr and the duration of mitosis is about 35 min

Induction of Parthenocarp in *Rosa arvensis* Huds. with Gibberellic Acid

As has been previously reported¹, parthenocarp may be induced in the two non-apomictic species, *R. rugosa* Thunb. and *R. spinosissima* L., by means of α -naphthaleneacetic acid, α -naphthaleneacetamide and 2,4,5-trichlorophenoxyacetic acid. Similar experiments were carried out in an attempt to induce parthenocarpic development in a third non-apomictic species, *R. arvensis*.

The auxin was applied in two ways to the unopened flower-bud, which was emasculated by cutting off the

Since the development of rosaceous fruit after fertilization is characterized by increase in cell size rather than in cell number, the properties demonstrated for gibberellic acid suggested that it might be effective in inducing parthenocarpic development. In February 1958 parthenocarpic hips of *R. rugosa* were produced in the greenhouse by the application of gibberellic acid and shortly afterwards similar results were recorded for *R. spinosissima*¹.

In June 1958, 200 flower buds on a bush of *R. arvensis* were emasculated and 10 per cent gibberellic acid in lanolin was applied. Control groups of normal and emasculated buds were also selected, it had previously been shown that the application of lanolin alone produced no response. Samples from each group were harvested at intervals for determinations of fresh and dry weight, and Fig. 1 shows the development of the different groups of hips in terms of average hip diameter and fresh weight.

The main period of fruit-drop in *R. arvensis* is 3–5 weeks after flowering, 46 days after treatment with gibberellic acid. 107 out of 150 hips were developing parthenocarpically, which represented a fruit-set of 71 per cent compared with 45 per cent for the normal, fertilized hips under these field conditions. None of the emasculated buds developed. Of the 57 parthenocarpic hips allowed to remain until maturity at 14 weeks after treatment, 48 had the appearance of normal, ripe hips while the other nine were smaller and not fully pigmented.

The *Triticum* coleoptile straight-growth test of Luckwill² showed that normal hips appear to contain two acidic, growth-promoting substances having R_F values of 0.1–0.2 and 0.4–0.5 in isopropanol/ammonia/water, and a neutral, growth-promoting substance with an R_F of 0.0–0.1 which is present in small quantities in the bud and flowering stages but which could not be detected 17 days after flowering, or in subsequent assays. None of these three substances was found in either parthenocarpic hips or emasculated controls, but a neutral growth-substance ($R_F = 0.4–0.6$) was present in the emasculated hips and an apparently identical substance was found in the parthenocarpic hips. A consistent growth-inhibitory effect was present in the tests, predominantly in the acid fraction and centred at $R_F 0.8$ in all stages

of normal, emasculated and parthenocarpic hips.

The relationship between achene development and variations in the amount of growth regulators will be reported elsewhere.

Fig. 1. The growth in terms of average diameter and fresh weight of normal hips, O—O, emasculated flower buds x—x, and emasculated flower buds treated with 10 per cent gibberellic acid in lanolin, ●—●.

'disk' (including the head of stigmas) immediately prior to treatment. In early experiments aqueous solutions of the auxins mentioned above and indoleacetic acid were injected into the cavity of the receptacle in concentrations ranging from 2 to 25 p.p.m. In later work the auxin was applied to the cut surface as a lanolin paste in concentrations of 0.025–1.0 per cent. Since *R. arvensis* differs from the other two species in having a much lower ascorbic acid content³, additional mixtures, including ascorbic acid, were used.

Almost all these experiments produced negative results, the emasculated control hips usually surviving longer than those treated with auxin. Out of a total of about 300 buds treated, only four showed any signs of growth, these had received the lowest concentration of auxins in lanolin and two of them had had ascorbic acid.

HÆMATOLOGY

Anti-A Hæmagglutinins from a Non-Leguminous Plant—*Hyptis suaveolens* Poit

CERTAIN plants, chiefly their seeds, contain agglutinins for the erythrocytes of various species. Whereas most plant agglutinins make no individual distinctions among human erythrocytes, some act selectively on one or other of the following blood group antigens¹ A, A₁, B, H and N. Except for separable anti-H and anti-B agglutinins from the seed capsule of certain species of *Eunymium* of the family Celastraceae, all specific seed agglutinins have hitherto been obtained from Leguminosae¹.

An anti-A agglutinin has now been found in the seeds of *Hyptis suaveolens*, Poit., of the genus Labiatae. The agglutinin works best when a fresh seed extract is tested on a flat tile which is gently and continuously rocked. Although it is not very avid when tested with erythrocytes suspended in isotonic saline solution, it agglutinates A₁ and A₁B cells strongly, A₂ weakly, and fails to agglutinate A₂B cells. Thus *Hyptis suaveolens* seed extract sharply differentiates A₁ and A₁B erythrocytes from those of the weaker subgroups of A and AB; however, it is not as satisfactory for this purpose as *Dolichos biflorus* seed extract², which is far more avid.

The *Hyptis suaveolens* agglutinin acts as strongly at 37° C or 4° C as at room temperature. It does not cross react with B or O cells after 24 hr at 4° C or when erythrocytes are suspended in albumin album, however, potentiates the agglutination of A₁ and A₁B cells. Agglutination is inhibited by A secretor saliva and by AB serum. A full description will be presented elsewhere.

The 'new' agglutinin is of special interest because it is the first seed anti-A (anti-A₁) agglutinin to be found outside the Leguminosae. The current trend is to confine the search for specific seed agglutinins to leguminous plants; wide examination of other plant families might be profitable.

I am grateful to D. S. Das for collecting the seeds and for technical assistance. The seeds were identified by the Botanical Survey of India, Poona.

Interaction of Erythrocytes and Endotoxins

CONSIDERABLE diversity of opinion exists as to the sensitivity of hæmagglutination tests. The discrepancy in results may to some extent be attributed to technical differences. The factors influencing the reaction, the elution of endotoxin *in vitro* and the uptake by erythrocytes *in vivo* have been examined using a dehydrated endotoxin derived from *S. typhi* (TO-901). This powder consisted of 88.5 per cent ash, 7.8 per cent moisture, 1.6 per cent protein, 2.3 per cent lipids and based on L-rhamnose hydrate as standard, 2.7 per cent rhamnose. If the method of calculation described by Webster *et al.*¹ is adopted the polysaccharide content is 14.3 per cent and the endotoxin approximately 20 per cent. The powder was dissolved in isotonic saline heated to 56° C for

30 min and stored at 4° C for at least 24 hr before use. The solution had a slight buffer action, pH 7.2. Erythrocytes from healthy rabbits were washed and measured with the hæmato-crit. A volume of 0.2 ml packed cells was used in most experiments.

Endotoxin was adsorbed on to the washed and measured erythrocytes at 37° C for 1 hr. The cells were then washed three times in 6-8 volumes of isotonic saline and accurately made up to a 20 per cent suspension. Agglutination was performed on slides, using 0.05 ml of sensitized erythrocytes and an equal volume of a diluted standard TO serum. The slide was agitated regularly and the test read after exactly 10 min.

The amount of endotoxin adsorbed on erythrocytes was dependent on both the absolute quantity of endotoxin available and on its concentration. The speed of the process was proportional to the concentration of endotoxin and related to the temperature, being five to six times faster at 37° C than at 4° C.

Erythrocytes coated with very small amounts of endotoxin were unagglutinable in antiserum, whereas those with greater quantities of endotoxin agglutinated readily. This afforded the basis for the determination of an 'erythrocyte-agglutinating unit', defined as the smallest amount of endotoxin, incubated with 2 ml of 10 per cent erythrocytes for 1 hr at 37° C, which rendered the cells agglutinable in standard serum diluted 1 in 10. One erythrocyte agglutinating unit was found to be equivalent to 0.16 mgm of the dehydrated powder. The quantity of crude endotoxin adsorbed on erythrocytes in these circumstances was 0.12 mgm, thus removing 75 per cent of endotoxin from the supernatant. Assuming the crude powder contains 20 per cent endotoxin it appears that 0.2 ml of agglutinable packed cells under our experimental conditions must be coated with a minimum of 24 µgm. of endotoxin.

Erythrocytes, initially sensitized with sub-agglutinable quantities of endotoxin, became agglutinable on subsequent exposure to endotoxin provided that the sum of the two doses constituted at least one erythrocyte agglutinating unit. Thus the erythrocytes appear to bind the adsorbed endotoxin quite firmly.

Assuming that the endotoxin was not removed or rendered undetectable except by fixation to erythrocytes the reduction in endotoxin content as measured by determination of the erythrocyte agglutinating unit on the supernatant, will be a direct, quantitative expression of adsorption. Experiments along these lines indicated that erythrocytes were capable of binding at least 200 times the minimum amount required for agglutination under standard conditions, that is to say 0.2 ml packed cells could adsorb more than 200 × 24 µgm or 4.8 mgm of endotoxin as calculated, corresponding to 2.2 per cent of their own weight.

Erythrocytes of the same batch, coated with amounts of endotoxin ranging from 1 to 200 erythrocyte agglutinating units, gave final agglutination titres against the standard serum ranging from 1/10 to 1/1,280. Hence, the titre of a given serum will vary according to the quantity of endotoxin adsorbed on to the cells. This may explain, at least partially, the discrepancy and inconsistency in results obtained by hæmagglutination tests, it could be overcome by rigorous standardization for which accurate measurement of endotoxin is essential.

Fluon of endotoxin at our experimental conditions (pH 7.2-7.3) was minimal. Erythrocytes coated with 1/5 times minimum agglutinating dose of endotoxin

were still agglutinable after 12 washings in saline at room temperature. Thus, on the assumption that the stability of an erythrocyte suspension is unaffected by washing, it may be concluded that elution is of a low order. Since this could not be measured in erythrocyte-agglutinating units, a technique for estimating smaller quantities of endotoxin in solution was provided by the construction of a dose-response graph in rabbits. The maximum antibody response, as measured by bacterial agglutination, was directly proportional to doses of crude endotoxin ranging from 0.01 μ gm to 1 mgm. Using the dose-response technique for endotoxin estimation, further studies on elution at room temperature showed that endotoxin was released, but that this did not amount to 1 per cent of the adsorbed endotoxin per equivalent volume of saline. Whether the eluted endotoxin originated from intact or disintegrated erythrocytes has not as yet been established, but it is noteworthy that the washings caused slight haemolysis.

Sensitized, washed cells inoculated intravenously into non-immune rabbits were highly antigenic. A single injection of a suitably adjusted erythrocyte suspension produced, in 7-10 days, agglutination titres up to 1:100,000. The serum of a rabbit previously immunized by endotoxin produced haemagglutination *in vitro* against its own sensitized cells. Haemolysis occurred on the addition of complement. Intravenous inoculation of 20 ml of 50 per cent suspension of these erythrocytes, which agglutinated *in vitro* with the recipient's serum, boosted the antibody production. The animals failed to produce an acute intravascular episode. Nor was there conclusive evidence of a haemolytic process as measured by serum bilirubin estimations and Schumm's test. This tolerance of what is a serologically incompatible transfusion is unexplained.

In vivo sensitization in rabbits was demonstrated by intravenous injection of large doses of endotoxin. The animals were bled 4 hr later and the erythrocytes, washed six times in excess saline, were inoculated intravenously into non-immune rabbits. They responded with a significant antibody production. Which part the adsorption *in vivo* plays in the defence against endotoxins has not as yet been established.

Details of these experiments will be published elsewhere.

BIOCHEMISTRY

Interaction of Sucrose Stearate with Starch

It is generally agreed that changes in the starch component of flour are responsible for the staling of bread¹. Following a report by Bohn² that the stearates are effective as anti-staling agents, a study of the interaction of starch with sucrose stearate, kindly

provided by Dr. J. H. B. de Vries, was made. Addition of a sucrose stearate solution to a 1 per cent solution of 'AnalaR' starch in 0.1 per cent sodium chloride resulted in the precipitation of some starch. The maximum amount of precipitate (about 20 per cent of the weight of starch) was obtained with concentrations of sucrose stearate above 0.06 per cent.

Extension of the study to undegraded starches (Table 1) showed that the amount of precipitate depended upon the type of starch. Fractionation of the potato starch into amylose and amylopectin³ followed by precipitation with excess sucrose stearate showed that most of the amylose but little of the amylopectin was precipitated (see Table 2). Treatment with excess sucrose stearate of an artificial mixture of amylose and amylopectin in the ratio in which they occur in starch gave a figure intermediate between that of the whole starch and that which would be expected on the basis of the separate amylose and amylopectin precipitations. These results indicate that the amylopectin is precipitated more efficiently in the presence of amylose than in its absence.

Table 1 PRECIPITATION OF STARCHES BY SUCROSE MONOSTEARATE

| Type of starch | Polysaccharide concentration (per cent) | Sucrose monostearate concentration (per cent) | Precipitate (per cent of polysaccharide) |
|-------------------|---|---|--|
| 'AnalaR' starch | 1.0 | 0.1 | 21.6 |
| Potato starch | 1.0 | 0.1 | 70.0 |
| Wheat starch | 1.0 | 0.1 | 92.4 |
| Waxy maize starch | 1.0 | 0.1 | 13.0 |

Table 2 PRECIPITATION OF STARCH FRACTIONS BY SUCROSE MONOSTEARATE

| Type of starch fraction | Polysaccharide concentration (per cent) | Sucrose monostearate concentration (per cent) | Precipitate (per cent of polysaccharide) |
|---|---|---|--|
| Potato starch | 0.4 | 0.04 | 72.7 |
| Potato amylose | 0.4 | 0.04 | 70.0 |
| Potato amylopectin | 0.4 | 0.04 | 11.1 |
| 20 per cent amylose 80 per cent amylopectin | 0.4 | 0.04 | 43.9 |

Controlled acid hydrolysis of potato starch showed that a high molecular weight was important in determining the amount of precipitate formed with sucrose stearate and it is likely that the low yield of precipitate from 'AnalaR' starch could be attributed to this factor.

A study of the change in diameter of wheat starch granules on heating in aqueous suspension in the presence and absence of sucrose stearate showed that the rate of swelling was reduced in the presence of sucrose stearate. From an examination of the change in turbidity on heating wheat starch suspensions (0.1 per cent), it appeared that in the presence of 0.01 per cent sucrose stearate the gelatinization temperature is raised about 10 deg.

As sucrose stearate is firmly bound by starch, it seemed likely that it would interfere with the starch/iodine reaction. This was shown to be so, and that iodine and sucrose stearate compete for the amylose fraction. There was no evidence for any marked interaction between sucrose stearate and amylopectin by this technique. It is possible that the stearate chain of the sucrose stearate mole-

cule occupies a position down the centre of an amylose helix, in the same way that iodine does¹

Influence of X-Rays on the Activity of Carbonic Anhydrase in Erythrocytes and on their Haemolytic Resistance

SINCE sickle cell anemia is possibly related to the activity of carbonic anhydrase¹, it is of interest to find some way of inhibiting the enzyme without altering the resistance of the cell membrane. Carbonic anhydrase is very stable² but its activity can easily be changed experimentally by adjusting the pH and temperature, or by adding sulphonamides or certain organic ions. All these factors, however, have a marked influence on hemolysis, whereas erythrocytes seem to be rather resistant to X rays³. We therefore decided to examine whether carbonic anhydrase could be inhibited by a dose of X rays which would have little or no effect on hemolysis.

For the determination of the enzyme activity we designed an improved Warburg technique⁴. This method is based upon measuring the rate of evolution of carbon dioxide when a bicarbonate solution is treated with a buffer and the enzyme. We calculated the unimolecular velocity constant of the reaction, which is also used as an index of activity by Mitchell, Pozzani and Fessenden⁵. The standard error of our measurements was 12 per cent and for the non-catalysed reaction 4 per cent. As a measure of the hemolytic resistance we used the hemolytic index⁶, the highest in conventional experimental conditions⁶, the highest dilution of lysin which produces 100 per cent hemolysis within 2 hr. The standard error of our hemolytic indices was 2.5 per cent. Suspensions of 10⁹ cells/cm³ in physiological saline solution were irradiated in vessels of 2 cm³, dose 100,000 r, instrument Philips 'Compacta', 210 kV, h.v.l. = 4 mm of aluminium, dose rate 6,700/min.

In non irradiated blood we found the following carbonic anhydrase activities, calculated per cubic centimetre of full blood: ox blood, 1.85 Mitchell units; human blood, 1.4; chicken blood 1.2. Irradiations of four samples of ox blood, two samples of human blood and two samples of chicken blood had no effect on the activity. Repeating this dose after 24 hr yielded no inhibition. Solutions of purified enzyme (Schering's 'Cataso', 0.1 per cent) treated in the same way, showed an inactivation of 20 and 50 per cent respectively. The fact that these high doses of X rays do affect erythrocytes in other respects was shown by their hemolytic index.

In our controls this was 13,300 with saponinum album (Morch), after irradiation the index was increased by 10 per cent and after the second dose of 100,000 r the increase was 17 per cent.

Our experiments confirm the great stability of carbonic anhydrase, and indicate that this stability is still greater inside the red blood cell. We found no decrease in activity of the carbonic anhydrase of erythrocytes after irradiation with 200,000 r. The hemolytic resistance of the cells was clearly diminished by this dose, so that it is possible that irradiation by X rays will permit us to modify the structure of the cell membrane without altering its carbonic anhydrase activity.

We wish to thank Prof. R. Ruysen for advice and encouragement and Prof. Van Vaeckenberg, who provided the necessary X ray equipment.

A Method for distinguishing between α - and β -Glycosides by the use of Plant Haemagglutinins (Lectins)

SEVERAL plant seeds contain proteins that agglutinate red blood cells^{1,2} as do many antibodies. For these proteins the name 'lectins' has been suggested³. They can be as specific as animal antibodies in that they react only with erythrocytes of certain blood groups. The ABO blood group specific lectins—as well as the ABO specific antibodies—are inhibited by some simple sugars, mainly components of blood group polysaccharides^{4,5}. Several 'unspecific' lectins are also inhibited by simple sugars, but these sugars are not necessarily components of blood group polysaccharides^{6,7}. The explanation of this phenomenon is that the sugars the structure of which most closely resembles the specific (sugar) group of the red cell receptor attach themselves to the active site(s) of the lectin molecule thus blocking them.

A monosaccharide as a rule retains its inhibiting power even when linked to other sugars through the hydroxyl group of the first (in ketoses the second) carbon atom⁸. The type of link, whether α or β , seems to be significant. In order to throw light on this problem, I made plant agglutinin inhibition tests by a method described in detail elsewhere⁹.

The following sugars were used in all experiments:
D glucose D glucosamine N-acetylglucosamine D

glucuronic acid, D-gluconic acid, D-xyllose, D-mannose, D-fructose, L-sorbose, D-galactose, D-galactosamine, N-acetyl-D-galactosamine, D-fucose, L-arabinose, D-talose, L-galactose, L-fucose, D-arabinose, D-ribose, D-digitoxose, L-rhamnose, maltose, sucrose, turanose, trehalose, cellobiose, gentiobiose, melibiose, raffinose, and lactose

Seeds of *Pisum sativum* L., *Cytisus sessilifolius* L., *Bandeiraea simplicifolia* Benth., and *Crotalaria juncea* L. were used. The lectin solutions were prepared by incubating a mixture of seed powder (1 part) and physiological saline (9 parts) for 2 hr at 37° C. After centrifugation the supernatant was used. 0.05 ml of seed extract containing 2-4 agglutinating doses of lectin and 0.05 ml of sugar solution (pH 7.0) in saline were mixed, and after 30 min incubation at 20° C 0.05 ml of a suspension containing 3 per cent human red cells in saline was added. After 2 hr further incubation at 20° C the tubes were read for agglutination. The quantitative inhibiting power of the sugars was measured by preparing two-fold serial dilutions of them.

The results are shown in Tables 1 and 2. The figures give the final concentration of sugar. Of the sugars tested (see above) only those which inhibit either *Pisum sativum* or *Cytisus sessilifolius* lectin at a concentration of 0.08 M are included in Table 1. The *Pisum* lectin is strongly inhibited by D-glucose, D-mannose, D-fructose and weakly by L-sorbose. The structural differences between the first three sugars are confined to carbon atoms 1 and 2. L-Sorbose differs from D-fructose only with regard to carbon atom 5, but its inhibiting activity is far lower. D-Glucuronic acid and D-gluconic acid are not inhibitory.

It will be seen from the second part of Table 1 that α -glucosides inhibit agglutination by *Pisum* extract as effectively as D-glucose, while β -glucosides are not inhibitory. Sucrose is not only an α -glucoside but a β -fructoside as well, however, the fructose

Table 1

| Sugar | Minimum amount of sugar (m moles/l) inhibiting the action of | |
|--------------------------|--|-------------------------------------|
| | <i>Pisum sativum</i> lectin | <i>Cytisus sessilifolius</i> lectin |
| D-Glucose | 1.25 | >80 |
| D-Glucosamine | 5 | >80 |
| N-Acetyl D-galactosamine | 2.5 | >80 |
| D-Mannose | 0.6 | >80 |
| D-Fructose | 2.5 | >80 |
| L-Sorbose | 40 | >80 |
| (Lactose) | >80 | 40 |
| Maltose | 1.25 | >80 |
| Sucrose | 2.5 | >80 |
| Turanose | 0.6 | >80 |
| Raffinose | 0.6 | >80 |
| Lactose | >80 | 5 |
| | | 40 |

that any of it is so

Table 2

| | Minimum amount of sugar (m moles/l) inhibiting the action of | |
|--------------------------|--|---------------------------------|
| | <i>Bandeiraea simplicifolia</i> lectin | <i>Crotalaria juncea</i> lectin |
| D-Galactose | 0.6 | 5 |
| D-Galactosamine | 5 | >80 |
| N-Acetyl D-galactosamine | 0.4 | |
| D-Lucose | 2.5 | 20 |
| L-Arabinose | 5 | 20 |
| D-Talose | 20 | |
| L-Rhamnose | 40 | >80 |
| α -Galactosides | 0.3 | 5 |
| β -Galactosides | 0.3 | 20 |
| Lactose | 20 | 1.25 |

part is not probably responsible for the inhibition, since another β -fructoside, raffinose, has no effect on *Pisum* lectin. An agglutination by *Cytisus* extract, on the other hand, is inhibited by β -glucosides but not by α -glucosides. The failure of glucose itself to inhibit the *Cytisus* lectin is difficult to explain unless it is due to the hexose molecule being too small.

It seems possible, on the basis of the above results, to ascertain the type of the glycosidic link (α or β) of D-glucose, perhaps also of glucosamine, acetylglucosamine, D-mannose, in disaccharides and other oligosaccharides the structure of which is only partially known.

There are other lectins (*Bandeiraea simplicifolia* and *Crotalaria juncea*) by means of which it seems possible to obtain information of the type of the D-galactosidic (and perhaps D-fucosidic, L-arabinosidic, etc.) link, even though the differences between α - and β -galactosides are less definite (Table 2) than differences between α - and β -glucosides (Table 1). Unfortunately the number of galactosides tested is small.

If need be, the determinations can be made with 0.01-1 mgm of sugar, and the solution need not be pure, many amino-acids and other sugars, for example, do not interfere. There are other methods of studying the nature of the glycosidic link, but the amount of sugar needed for enzymatic or polarimetric studies is greater. The information obtained by chromatographic or infra-red spectrographic studies is limited unless an adequate stock of reference compounds is available.

Of the seeds quoted above only those of *Bandeiraea simplicifolia* may be difficult to get. The rest are obtainable from many seed shops, and can even be replaced by other related species. The *Bandeiraea* lectin is blood group B specific—it can be used with B erythrocytes only, and *Cytisus* lectin is O(H) specific—it should be used with O cells. The other lectins can be used with red cells of any blood group.

The ability of lectins to differentiate between α - and β -glycosides supports J. Lederberg's (personal communication) suggestion that there is some connexion between them and plant glycosidases. Lectins are not, however, likely to be true glycosidases because (a) they are present in ungerminated seeds and their amount does not increase appreciably after germination, (b) there is no correlation in occurrence between lectins and glycosidases in plant species, and (c) several purified lectin preparations have been found not to hydrolyse the disaccharides which inhibit agglutination.

The monosaccharide specificity of lectins seems to be less definite than that of glycosidases, though

glycosidases are not strictly specific, the members of a certain homomorphous sugar series (sugars with an identical pyranose or furanose ring) behave more or less alike as substrates of glycosidases³, but many lectins are inhibited by members of two homomorphous series. These series can differ with regard to the substituents of carbon atom 2. Thus *Phaseolus* lectin is inhibited by D-glucose and D-mannose. *Bandeiraea* lectin by D-galactose, D-fucose, L-arabinose and D-talose (see above) and *Lotus tetragonolobus* lectin by L-galactose, L-fucose, D-arabinose and D-deoxy-L-talose⁴. The substituents in carbon atoms 3 and 4 seem to be of the greatest importance to the capacity of monosaccharides to inhibit lectins, a view which was expressed six years ago by Morgan and Watkins⁵ with regard to *Lotus tetragonolobus* lectin.

I wish to thank Mr E. R. Vaughan, curator, Botanical Garden, University College of Ghana, who kindly sent me several samples of *Bandeiraea simplicifolia* seeds.

Reactivity and Interrelationship of Intermediates in the Hydrolysis of p-Nitrophenyl Acetate Catalysed by Chymotrypsin

KINETIC studies by Gutfreund and Sturtevant¹ suggest that p-nitrophenyl acetate reacts with chymotrypsin rapidly at a pH greater than 6.5 to

form monoacetyl chymotrypsin (AC-I) and that AC-I is then deacylated slowly. The kinetic observations are consistent with the esterification of a single serine hydroxyl of the enzyme². In contrast, spectroscopic studies³ of the deacylation of monoacetyl chymotrypsin formed at pH 5.0 and isolated according to the procedure of Balls and Wood⁴ (AC-A) show that when AC-A is brought to pH 9.0, a rapid increase in absorption at 245 mμ occurs which is followed by slow decay of the absorption peak. Since both the absorption peak and its rate of decay appeared characteristic for N-acetyl imidazole, Dixon and Nourah⁵ suggested that the deacylation of monoacetyl chymotrypsin proceeds by a rapid intramolecular shift of the acetyl group from a serine oxygen to an imidazole nitrogen of the enzyme (AC-II) and that the rate-limiting step of the enzymatic reaction is the base-catalysed hydrolysis of N-acetyl imidazole. Recently however we have observed⁶ that AC-I and AC-A are deacylated at different rates as measured by the liberation of p-nitrophenol from p-nitrophenyl acetate catalysed by AC-I and AC-A and that AC-I is converted to AC-A under the conditions used in the isolation procedure⁶.

The result of investigations reported below further delineate the differences between AC-A and AC-I and suggest an interrelationship between AC-A, AC-I and AC-II as well as a structure for AC-A. The experiments illustrated in Fig. 1 indicate that AC-A (salt free α-chymotrypsin, recrystallized three times, gift of the Sigma Chemical Co., St. Louis, Missouri) cannot be deacylated via a single intermediate which decomposes with a single rate constant identical with the rate of decay (1.7×10^{-3} sec⁻¹)⁶ of the 245 mμ absorption peak. Curve 1 represents α-chymotrypsin preacylated for 10 min. at pH 5.0 with 100 equivalents of p-nitrophenyl acetate and mixed at zero time with buffer such that the final pH was 8.0. Zero-order steady state liberation of p-nitrophenol is observed within 15 sec. The rate of deacylation (k_d) of this enzyme (AC-I) calculated from the observed rate of liberation of p-nitrophenol is 1.6×10^{-3} sec⁻¹ at 15°C. Curve 2

represents an experiment in which AC-A was mixed at zero time with p-nitrophenyl acetate at pH 8.0. The rate of liberation of p-nitrophenol during the first 30 sec. is only about 70 per cent of the rate observed in curve 1 (AC-I) and essentially the same as AC-I after 300 sec. The deviation from zero-order kinetics observed during the first 300 sec. of the reaction of AC-A with p-nitrophenyl acetate is interpreted as indicative of the rates of reactions involved in the conversion of AC-A to AC-I. These reactions are presumably the deacylation of AC-A and its reacylation at pH 8.0 to form AC-I. However, the rate of conversion of AC-A to AC-I is incompatible with the complete deacylation of AC-A via the imidazole intermediate as can be seen

Fig. 1. The liberation of p-nitrophenol in the catalytic hydrolysis of p-nitrophenyl acetate by α-chymotrypsin and monoacetyl-α-chymotrypsin preparations. Curve 1: α-chymotrypsin, 0.12 M, in 0.1 M Tris-(hydroxymethyl)-aminomethane-maleate buffer, pH 8.0 at 15°C. Total ionic strength 0.12 M. $[E]_0 = 2.1 \times 10^{-3}$ M, $[S]_0 = 1.7 \times 10^{-2}$ M. Curve 2: monoacetyl-α-chymotrypsin, 0.12 M, in 0.1 M Tris-(hydroxymethyl)-aminomethane-maleate buffer, pH 8.0 at 15°C. Total ionic strength 0.12 M. Curve 3: α-chymotrypsin, 0.12 M, in 0.1 M Tris-(hydroxymethyl)-aminomethane-maleate buffer, pH 8.0 at 15°C. Total ionic strength 0.12 M. Curve 1: α-chymotrypsin preacylated for 10 min. at pH 5.0 with 100 equivalents of p-nitrophenyl acetate at pH 5.0 and 15°C, and then mixed with buffer at zero time to bring the pH to 8.0. Curve 2: isolated monoacetyl-α-chymotrypsin (ref. 4) (AC-I) curve 3: a calculated curve for the catalysis of p-nitrophenyl acetate by a monoacetyl enzyme which is deacylated with a rate of 1.7×10^{-3} sec⁻¹.

Activation of Staphylococcal-free Coagulase by Purified Human Prothrombin

FREE coagulase¹ is an extracellular protein produced by pathogenic staphylococci², which reacts with coagulase activator³, present in the plasma of certain animal species, to yield an active material capable of clotting any fibrinogen¹. The active material has been called activated coagulase⁴ and has been shown recently, by a study of the kinetics of the reaction between purified free coagulase⁵ and an impure preparation of coagulase activator, to be produced during the enzymic degradation of the former by the latter. This work, however, shed no light on the vexed problem of the nature of coagulase activator²⁻⁵, owing to the inhomogeneity of the coagulase activator preparation employed.

Through the kindness of Dr F Duckert of the Medizinische Universitätsklinik, Zurich, we have been able to repeat some of these experiments, using, as the source of coagulase activator, a highly purified sample of human prothrombin prepared by chromatography on barium sulphate and 'Hyflosupercel' by a slight modification of the method used by Duckert, Koller and Matter¹⁰. This material contained about 1,000 units of prothrombin and 160 units of coagulase activator per mgm protein, and was thus enriched between 600 and 700 times (Dr Duckert, private communication).

Solutions of prothrombin in phosphate buffer (0.07 M disodium hydrogen phosphate-potassium dihydrogen phosphate, pH 6.8) were incubated at 37° C with various concentrations of free coagulase and activated coagulase was assayed in the mixtures as already described⁴. The results, which are summarized in Table 1, are essentially similar to those obtained previously⁴ and demonstrate the instability of activated coagulase under these conditions. The concentration of activated coagulase produced and the length of time before its exhaustion are directly dependent upon the initial concentration of free coagulase in the mixture. These facts, together with the finding that the exhausted mixtures still contain coagulase activator but no free coagulase, confirm that free coagulase is enzymically degraded by coagulase activator.

Table 1 FORMATION AND DESTRUCTION OF ACTIVATED COAGULASE IN MIXTURES CONTAINING A CONSTANT AMOUNT OF PURIFIED HUMAN PROTHROMBIN AND VARIOUS AMOUNTS OF FREE COAGULASE

Values given are for the concentration of activated coagulase (units/ml)

| Incubation time of mixture at 37° C (hr) | Concentration of coagulase (units/ml) added to an equal volume of purified human prothrombin (250 µgm/ml) | | | |
|--|---|-----|------|------|
| | 25 | 10 | 5 | 2 |
| 0 | 3.3 | 1.0 | 1.2 | 0.5 |
| 1 | 4.3 | 2.8 | 1.4 | 0.0 |
| 2 | 4.0 | 2.8 | 1.4 | 0.0 |
| 3 | 4.0 | 2.4 | 1.4 | 0.5 |
| 4 | 3.8 | 2.4 | 0.9 | 0.3 |
| 5 | 4.3 | 1.5 | 0.8 | 0.25 |
| 6 | 4.0 | 1.4 | 0.0 | 0.23 |
| 8 | 3.0 | 0.8 | 0.5 | 0.17 |
| 22 | 1.5 | 0.9 | 0.34 | 0.08 |

After incubation for 22 hr the mixtures were divided into three portions and to (a) was added an equal volume of prothrombin 190 µgm/ml, to (b) an equal volume of coagulase 25 units/ml and to (c) an equal volume of buffer. They were then incubated for 10 min and the activated coagulase content measured as before.

| | a | b | c |
|------|-----|------|------|
| 0.5 | 0.5 | 0.12 | <0.1 |
| 2.7 | 3.1 | 2.7 | <0.1 |
| 0.13 | 0.5 | 0.13 | <0.1 |

In view of the highly purified nature of the human prothrombin used as a source of coagulase activator, it seems likely that the two are identical. This suggestion is supported by the observation that the ratio of prothrombin to coagulase activator in normal human plasma is identical with that in the present highly purified preparation of prothrombin.

CHEMISTRY

Separation of Polyvinyl Chloride and Polyvinyl Acetate by Chromatographic Methods

THE material used in this work was known to contain at least two co-polymers. A method of separation was sought which would not require a complex chemical procedure. The separation of high polymers by chromatographic means was carried out by Claesson¹, while separations on columns packed with carbon black were attempted by Landler².

It was found that absorption decreased with increased molecular weight. A column of activated charcoal was packed and saturated with methyl iso-butyl ketone. The mixture containing the two co-polymers in this solvent was added to the top of the column and washed with the solvent. After a few minutes, the elutant was giving a positive test for chloride. After 1 hr washing the fractions began to give positive acetate results.

In order to attempt some form of confirmation, a method of separation was devised by paper chromatography.

The mixed co-polymers in solution were spotted on to a strip of Whatman's No. 4 filter paper and air-dried. This strip was then allowed to run at room temperature for 45 min, using once again methyl iso-butyl ketone as a solvent. The strip was then air-dried and sprayed with a solution of one part BDH Universal indicator and one part distilled water. The whole strip was then washed in distilled water and dried. The acetate spot remained stationary, while the chloride moved with the solvent front. *R_F* values were zero for chloride 0.985 and 0.0 for the acetate. Both spots were eluted, yielding positive tests for acetate and chloride, respectively.

To determine the accuracy of the separation, two pure polymers of acetate and chloride were mixed in the solvent. These were then spotted on to a No. 4 filter paper and run as a control. Identical results were obtained as with the mixed co-polymers.

This method is not suggested as an analytical procedure but as a rapid means of separating mixed polymers.

Further details of this work will be published elsewhere

A New Method for working up Processing Mixtures containing Anhydrous Aluminium Chloride

On working up the mixture in order to isolate the products of reactions catalysed by anhydrous aluminium chloride, the first step is usually decomposition with an ice acid mixture¹. However, difficulties are often encountered in the separation of the aqueous phase containing the aluminium salts, due to the formation of stable emulsions. This makes the repeated washing of the organic phase necessary to ensure complete extraction of the aluminium salts, a rather tedious operation.

In our experiments we found that a solution of sodium fluoride could be used with advantage at this stage, and also to eliminate interference during later stages. The favourable effect is due to the formation of the complex Na_2AlF_6 , which is soluble in water. The advantages of the method may be summarized as follows:

1 The aqueous solution, when it contains sodium aluminium fluoride, is readily and quickly separable from the organic phase, in our experiments, nitrobenzene.

2 When the second step of working up the reaction mixture is steam distillation of an alkaline solution no separation of the aqueous phase is necessary. Further as the aqueous phase is already alkaline, no addition of alkali is required to secure the alkaline reaction of the medium.

3 When a neutral solution is wanted during processing, a slightly acidified solution of sodium fluoride can be used. The exact amount of hydrochloric acid necessary can be determined by blank tests on a solution of anhydrous aluminium chloride at the same concentration as the reaction mixture. These blanks are of great importance as the quantity of acid required depends on the quality of the sodium fluoride.

4 Since the method facilitates the working up and analysis of very small quantities, it is particularly suitable for micropreparation and kinetic studies. Although stoichiometrically 6 moles of sodium fluoride are required for each mole of aluminium chloride, we find it best to use at least 7 moles of the reagent.

As an example, part of an unpublished kinetic study will be given here, where a quantitative determination of the ketone was carried out on the mixture obtained by the Fries rearrangement of thymyl acetate in nitrobenzene in the presence of aluminium chloride.

Preparation of thymyl methyl ketone 2.4031 gm (12.4 mmoles) of 99.14 per cent thymyl acetate was treated with a solution of 4.17 gm (31.3 mmoles) of anhydrous aluminium chloride (B.D.H.) in nitro-

benzene, and the mixture was made up to 20 ml with nitrobenzene. The mixture was allowed to stand for 5 hr in a thermostat of 40° C, and then an aliquot of 2 ml was transferred by pipette into an equal volume of ethanol. This mixture was refluxed for 30 min with 30 ml of a solution of sodium fluoride (containing 35 gm sodium fluoride) 3 ml of 1 N sodium hydroxide and 24 ml of ethanol. After cooling the solution was made up at room temperature to 100 ml with water and allowed to stand overnight in a glass cylinder, 2.5 cm in diameter when nitrobenzene separated. A portion of 50 ml was withdrawn from the clear supernatant with a pipette treated with 3 ml of 1 N hydrochloric acid and distilled until the temperature of vapour reached 98° C (approximately 5 min.). The residue was allowed to stand for 2 hr in an ice box, then the precipitated crystals were filtered through a glass filter, dried at 110° C for an hour and weighed together with the filter. Thymyl methyl ketone was then separated from inorganic contaminants by treating the filter with 3-5 ml of hot ethanol. After drying the filter for 20 min. at 110° C, it was again weighed. The difference was 0.0881 gm. The almost white crystalline product obtained by evaporating the ethanolic solution had a melting point of 122.5-125° C. For $\text{C}_{11}\text{H}_{18}\text{O}_2$, molecular weight 192.25, calculated (per cent): C 74.07, H 8.39, found (per cent): C 74.95, H 8.07.

The ketone obtained by the classical Rosenmund method² was nearly black, m.p. 116-122° C.

The correction for the solubility of the ketone gives a gross yield of 0.092 gm., thus by the Fries rearrangement a yield of 94.6 per cent was obtained. With suitable modifications the quantity of unconverted ester can also be determined by titration³.

We wish to thank the Hungarian Academy of Sciences for a grant and the Microanalytical Laboratory of the Institute of Organic Chemistry of the University of Szeged for carrying out the microanalyses.

Calculation of a 'Cosmic Ray Age' for the Iron Meteorite 'Carbo'

THE potassium of the iron meteorite 'Carbo' compared with ordinary potassium is substantially enriched in the isotopes potassium-40 and 41 as shown in the recent isotopic analysis by Voshage and Hintenberger¹. At least 15 per cent of these isotopes in their sample of Carbo appear to have been produced through the action of cosmic rays. Stoener and Zähringer² found that the concentration of potassium may vary considerably within an iron meteorite. Their analyses were based on the detection of potassium 41 and the β ion that the potassium had the same level as terrestrial potassium of 0.031 p.p.m.

of potassium from one sample is typical of 'Carbo' and is corrected to 0.012 p.p.m. in order to fit the new isotopic analysis, the potassium produced by spallation is at least 4.6×10^{-11} mole/gm. The total ion beam in the Voshage and Hintenberger analysis indicated that the concentration of potassium-40 alone is even greater than 1.8×10^{-12} mole/gm. The amount of potassium produced by spallation is probably about 10^{-11} mole/gm. This figure is quite compatible with that of 1.1×10^{-10} mole/gm for the helium-3 content² because the cross-section for the formation of potassium, including the contribution from argon-39 and calcium-41, seems to be³ about 40 mb, and the measured cross-section for the production of helium-3 (with hydrogen-3) by means of 3 BeV. protons on iron is approximately⁴ 340 mb. The neon also formed by spallation has a concentration⁵ of 5.8×10^{-12} mole/gm, which is comparable with that indicated for the potassium.

Radioactive species formed by spallation have been used to estimate the production rate of stable isotopes by cosmic rays. Radiation ages have been calculated in this way for meteorites from their helium-3 and argon-38 contents⁶. The combination of stable isotopes of potassium with the relatively long-lived potassium-40 may also be used to calculate a 'cosmic ray age', Δt in the following equation

$$\frac{1 - e^{-\lambda \Delta t}}{\Delta t} = \frac{\lambda K_m^{40} (\sigma_{39} - R\sigma_{41})}{\sigma_{40}(K_m^{39} - RK_m^{41})}$$

The relative abundances of the potassium isotopes used are $K_m^{39} = 0.795$, $K_m^{40} = 0.048$, and $K_m^{41} = 0.157$, as reported by Voshage and Hintenberger¹ for the meteorite 'Carbo'. The total decay constant, λ , is taken as $0.529 \times 10^{-9} \text{ yr}^{-1}$. R is the ratio of K^{39}/K^{40} in ordinary potassium.

In addition to the usual assumption regarding a constant cosmic ray flux, some knowledge of the cross-sections for the formation of the potassium isotopes is required. The cross-section versus mass curves for argon formed by high-energy protons on iron and copper are well defined experimentally (refs 3 and 4 and Bieri, R. H., personal communication). The curves are similar and are skewed towards the side of the neutron-rich isotopes. The known isotopes of potassium suggest that the spallation curve of this element is similarly asymmetrical and that the production cross-sections for potassium-40 and -41 are rather large and approximately the same.

Barr³ has estimated the approximate production cross-sections for the isotopes potassium-39, -40 and -41 for 5.7 BeV protons on copper. These cross-sections are 5.2, 9.4 and 9.2 mb, respectively. He inferred them from his measurements of the yields of more than fifty radioactive isotopes produced by the spallation of copper. The observed cross-sections for potassium-42 and -43 were 5.4 and 1.1 mb, respectively. Other spallation products such as argon-39 and calcium-41 contribute significantly to the formation of potassium. The cross-sections for the formation of potassium estimated from Barr's work then become $\sigma_{39} = 14.8$, $\sigma_{40} = 9.4$, and $\sigma_{41} = 14.7$ mb.

The radiation age calculated from the preceding values is $0.6 \times 10^9 \text{ yr}$. It is obvious in the above equation that the value for σ_{39} is comparatively insignificant. This figure may be incorrect by a factor of 2 without influencing the value of the right side of the equation by more than 10 per cent. The relative values for σ_{40} and σ_{41} are important. A

difference of even 20 per cent in their ratio affects the radiation age by 1×10^9 years. This seems to be approximately the uncertainty in this radiation age of 'Carbo', but the relative ages of iron meteorites may be determined with much greater precision. For the radiation age from the potassium to be 4.6×10^9 years, or the same as the lead-lead age^{7,8} and the rubidium-strontium age^{9,10} of stone meteorites, σ_{41} would have to be about one-half the value for σ_{40} . It should be noted that contamination will have a negligible effect on the radiation age as long as the observed abundance of potassium-40 is much greater than the potassium-40 in ordinary potassium.

The cosmic ray age calculated here for 'Carbo' is essentially the same as its estimated cosmic ray helium age of 0.85×10^9 years¹¹. The potassium-argon ages of several stone meteorites are also quite similar. The chondrites 'Kunashak' (grey variety) and 'Pervomaiskii Poselok' (grey variety) have ages of 0.70×10^9 and 0.64×10^9 years, respectively¹². The two shergotites 'Padvarninka' and 'Shergotty' have ages of 1.0×10^9 years¹³ and 0.56×10^9 years¹⁴, respectively. It seems that the stone meteorites belong to two groups, one with radiogenic helium ages of 4×10^9 years, the other with ages of about 0.5×10^9 to 1×10^9 years¹⁴. Helium probably has been lost from the meteorites of the latter group. The potassium-argon ages for the same meteorites clearly indicate some loss of argon¹⁴.

The accuracy of the cosmic ray age calculated from the potassium produced by spallation depends principally upon how well the ratio of the formation cross-sections for potassium-40 and -41 is known and the constancy of the cosmic ray flux. Nevertheless, this age of 0.6×10^9 years agrees remarkably well with independent age determinations for this meteorite and for other meteorites. Evidence is rapidly accumulating for the break-up of solid bodies and for the presumably related heating of at least some of the meteorites between 0.5 to 1.0×10^9 years ago. The comparison of potassium analyses from other iron meteorites may help to answer the question of whether these processes occurred throughout approximately half a thousand million years or during a much shorter interval.

I wish to thank Dr. R. H. Bieri and Dr. J. Geiss of this Institute for many discussions. This study was supported by a grant from the U.S. National Science Foundation.

Refraction of Very High Frequency Radio Signals at Ionospheric Heights

PEOPLE engaged in radio tracking of space vehicles are well aware of the fact that the Earth's atmosphere may cause serious refractive errors in the elevation angle determination. It is also generally accepted that refractive errors rapidly decrease with an increase in the elevation angle, and become virtually negligible above 10 or 15 degrees. In the case of radio astronomy, this is quite true. However, in the case of space-vehicles which travel in the immediate vicinity of the Earth, this is not the case. The refractive errors due to the troposphere rapidly decrease with the elevation angle, while those due to the ionosphere initially increase with the elevation angle, and then gradually fall off. This behaviour of ionospheric refraction is a necessary consequence of the spherical geometry. The value of the elevation angle at which the maximum ionospheric refractive error occurs lies typically between 100 and 200 milliradians. The exact expressions are rather involved, but it can be shown that the value of this angle is roughly proportional to the square root of the height of the layer. The maximum value of the ionospheric refractive error is about 10-15 per cent higher than its value for a tangentially departing ray.

Fig 1 shows a plot of the elevation angle error δ for realistic models of the ionosphere and troposphere. The tropospheric calculations were based on radio sonde data. The ionospheric calculations were based on a model of electron density profile which was parabolic below the region of the maximum density

and was represented by the hyperbolic secant above the maximum. The constants of the hyperbolic secant were adjusted so that the profile and its derivative were continuous everywhere, and the total electron content above the maximum was three times as large as below it. This is in accord with experimental data based on Faraday rotation measurements.¹ Details of the computational techniques are described elsewhere.²

For the purpose of the accompanying illustration, the ionospheric constants were adjusted as follows: height of the base 200 km, half thickness 100 km, critical frequency 14 mc, signal frequencies 50 and 100 mc. The target height for which the refractive errors were computed was 300 nautical miles.

Examination of Fig 1 shows that at very low angles of elevation α_0 , the tropospheric refraction contributes appreciably to the refractive error while at higher angles, the ionospheric factors predominate. The peculiar behaviour of the ionospheric refraction manifests itself by the presence of the shoulder which is especially prominent at 50 mc, and also by the fact that the refractive error decreases more slowly with the elevation angle than might have been expected from the study of the refraction of radio stars.

Near Infra-Red System of Nitrogen

In the course of studying the molecular spectrum of nitrogen under various excitation conditions Carroll and Savers¹ discovered a new triplet transition in the near infra red. Only one band was observed as the spectral region of interest was dominated by bands of the first positive system. A spectrogram of the new band was given together with measurements of the four strongest heads at 8265.5, 8283.8, 8293.3 and 8310.6 Å. The structure of the band was obviously complex, and it was suggested by Carroll and Savers that the transition might be $\pi^1 - \pi^2$.

More recently Kistiakowsky and Warneck² have reported bands of nitrogen in the infra red, and these observations have been extended by LeBlanc, Tanaka and Jursa³, who studied the emission from afterglows in argon-nitrogen mixtures at low temperature. They also made a preliminary vibrational analysis and showed that the lower state was most probably $B^2 \Sigma^-$.

There is no doubt that the new system is the same transition as that reported by Carroll and Savers. This is proved by (a) the close similarity in structure between the 8265.5 Å band on Carroll and Savers's spectrogram and the bands in the spectrogram given by LeBlanc, Tanaka and Jursa, and (b) the agreement between the measurements of corresponding heads in the 8265.5 Å band and the $(n+1) - 1$ band of LeBlanc, Tanaka and Jursa.

As the new system is of both theoretical⁴ and astrophysical⁵ interest the 8265.5 Å band has recently been investigated in the large dispersion. It was

Fig 1

photographed in the second order of the 21-ft grating in the Physics Department of University College, Dublin, and despite the weakness of the band and the presence of the first positive system, a rotational analysis proved possible. Three components were found, each consisting of a fairly strong P , Q and R branch together with a number of weaker satellite branches. A detailed examination of the results shows unambiguously that the upper state is of species $^3\Sigma_u^-$. A preliminary value of B_{n+1} determined from the Q branches alone gives 1.38_6 cm^{-1} . The analysis also verified beyond doubt that the lower state of the 8265.5 Å band is the level $v = 1$ of $B^3\Pi_g$. This is shown by the excellent agreement between the combination differences derived from the present analysis and those formed from the data on the 1-0 band of the first positive system⁶.

The vibrational numbering of the levels in the $^3\Sigma_u^-$ state is not known with certainty at present. However, one can say that the $v = 0$ level cannot lie above about $71,700 \text{ cm}^{-1}$ and that it very probably lies within a few vibrational quanta of this value. Now Mulliken⁴, in his theoretical work on nitrogen, has predicted that a $^3\Sigma_u^-$ state, with a B value of approximately 1.47 cm^{-1} , should occur at about $70,700 \text{ cm}^{-1}$. It is seen that the results of the present work are in satisfactory agreement with Mulliken's theoretical predictions.

A full account of the above work will be published elsewhere in the near future.

Luminous Spots on Electrodes in Insulating Oil Gaps

IN 1955 we reported the observation of luminous spots on electrodes in transformer oil¹. The spots were detected by a photographic plate in the oil between the electrodes with application of a c and d c voltage stresses for 2-30 min. The oil was usually degassed but not filtered. The luminous spots occurred at random on the surface of a plane electrode and were more concentrated at sharp edges. One of the electrode systems used was an American Society for Testing Materials oil-breakdown test-cup. The threshold average electric stress seemed to be of the order of 50 kV/cm minimum. At the time of those experiments it was not known whether these luminous spots were due to discharges in tiny bubbles or to another cause.

Since those preliminary experiments, more refined and efficient techniques have been used in the investigation of these luminous spots, whereby the electrodes are observed face on through a glass window coated with transparent semiconducting tin oxide. Microscopic examination has shown that, while bubbles do occur sometimes at high voltages under low hydro-

static pressures, or with fibres present, bubbles are not responsible for the luminous spots observed on electrodes in well-filtered, degassed oil. The luminous spots have been shown to occur only at the negative electrode with d c stresses and are therefore attributed to fluorescence of the oil molecules excited by field-emitted electrons from points of high localized electric stress on the electrodes. They have been detected by 10-min exposures with Ansco Super Hypan Film (ASA 500) in a camera having an $f/2$ lens opening at a distance of about 5 in. It is believed that these luminous spots are similar to the luminosity reported seen by Darveniza² at 600 kV/cm, but detected here at much lower average electric stresses. The threshold voltage stress seems to be of the order of 50-250 kV/cm, depending on the degree of polish of the electrodes and filtering of the oil. The local electric stress is very likely 10 or more times higher.

M. Wachtel (Westinghouse Research Laboratories, private communication) and Llewellyn-Jones³ have reported electron field emission into a vacuum or low-pressure gas at average electric stresses of the same order as used here.

The occurrence of luminous spots is not significantly affected by applied hydrostatic pressure from 10 mm mercury to 2 atmospheres. They also occur with a c voltages between glass surfaces, indicating that field emission occurs from glass surfaces. The luminosity is not affected by an efficient additive, benzil, reported by Basseches and McLean⁴ to prevent gassing.

It is believed that observation of these luminous spots assists in explaining the statistical effect of electrode area (and volume) on breakdown, particularly in commercial tests, and the dependence of long time a c electric strength on time of voltage application. It also suggests the origin of the development of gas (hydrogen) in stressed oils, since the electrons exciting fluorescence (requiring about 3 eV) may also have or gain by acceleration sufficient energy to decompose the hydrocarbon oil molecules (requiring about 4 eV).

Compaction of Briquettes

WHEN a powder is compacted by a simple application of pressure, the density and strength of the compact so formed (measured after the pressure has been released) are determined by the pressure used, but ultimately they approach limiting values which are not exceeded by further increasing the pressure. The limiting density of the compact falls short of the density of the material of the powder by an appreciable margin, say 4-20 per cent, depending on the material used (Fig. 1).

This failure to achieve complete compaction arises in two ways. First, as the briquetting pressure is applied it is opposed by forces set up in the powder

Fig. 1 Betteshanger coal relationship between briquetting pressure and density of briquette

and upon the walls of the mould, which resist the movement of the particles and which resist the deformation of individual particles, these forces prevent intimate contact between the particle surfaces. Secondly, as the external pressure is removed the deformed particles recover their shape elastically in part at least, and the compact expands and the voids within it increase. A large elastic recovery is associated with a weak compact.

It has been found that if the powder compact, while still under load, is subjected to shear strain, (as for example in a rotary shearbox as sketched in Fig. 2) there is a further compaction without any further increase in pressure being required. Also, the elastic recovery of the compact when constraints are removed is reduced. The compact made in this way is stronger than one made by simple pressing at the same pressure, and may possess greater density and strength than the limiting values obtained by simple pressing. Whether the compact is made by simple pressing or by introducing additional shear

strain under load, the strengths and densities are still related by the same single curve. The gain in strength may be substantial, and with coal powders a five fold increase has been attained. The full benefit is obtained only if the shear strain is introduced under maximum load (Fig. 3).

The response to the introduction of additional shear strain under load varies with the material. In a material such as Plasticene, which deforms plastically very readily and which has negligible elastic recovery, the process offers no advantage. Natural graphite powder also compacts readily, and reduces to a compact of about 4 per cent porosity by simple pressing, here again there is little advantage in applying extra shear strain which may do more harm by disrupting the briquette than good by compacting it. At the other extreme anthracite powder which shows an elastic recovery of 30 per cent while still in the die in which it has been pressed forms no compact at all with or without extra shear strain. The advantage of the process is found with materials lying between these extremes. The coal, the properties of which are illustrated in Fig. 3, is an example, the introduction of extra shear strain improves the compaction of the final briquette by about 10 per cent porosity and the strength by a factor of 3-5.

Fig. 3 Sherwood coal relationship between briquetting pressure, shear strain, strength and porosity (shear strain introduced in cycles of amplitude 6°)

The adhesion of particles in these non metallic compacts is not yet fully understood nor is the action understood whereby shear strain improves the adhesion. The fact that a single strength-density relationship applies to all compacts made from a given powder, with or without extra shear suggests that no new mechanism of adhesion is introduced by shearing.

Association between Colour of the Iris of the Eye and Reaction to Dental Pain

AN association has been found to exist, in Australians of European stock, between the colour of the eyes and the reaction to pain resulting from dental cavity preparation.

At the present stage of this study, examination has been made of 403 consecutive subjects whose teeth were being prepared for filling, the cavities being cut by means of the Borden high-speed air-rotor apparatus. Their ages ranged from three years to more than fifty years.

The pain reaction of each subject was assessed, four classes being used: subjects that showed (a) no pain reaction during the preparation of the cavity, (b) a slight reaction, (c) a marked reaction and (d) those whose reaction was so great as to require the injection of a local analgesic. After having recorded the pain reaction of a subject, the colour of the iris was observed, nine categories, ranging from blue to dark brown, being recorded. The pain-reaction classes were given arbitrary values of 0-3, and the colours of the iris, values of 1-9.

The association between these factors is highly significant, but, of course, is considered to be due to their joint association with other factors. The accompanying graph (Fig. 1) of mean values displays the association between pain reaction and colour of iris.

Each point of the graph is based on more than 40 observations, with the exception of the last three, for only 11 subjects were seen with light brown eyes, 23 with brown and 28 whose irises were dark brown.

Judgement of the reaction to pain is based on 12 months use of this new apparatus (Borden high-speed air-rotor), and on more than twenty years' clinical experience, nevertheless, it is acknowledged that both types of observation are open to criticism owing to their subjective nature. However, a test to establish the reproducibility of the results was satisfactory, for out of 136 subjects that were re-assessed between one and four weeks after the original examination, the same values were obtained for the colour of the eyes in 115 cases, and for the pain reaction in 114 subjects. Both for colour of iris and for pain reaction, the mean of the discrepancies between each pair of results was non-significant, the mean discrepancies were, pain reaction 0.02, iris colour 0.04.

Approximately 13 per cent of the total number of subjects required the injection of a local analgesic for cavity preparation, a similar percentage being found

Fig. 1 Association between the colour of the iris and the reaction to pain resulting from dental cavity preparation

in the group of subjects formed by adding the results of those whose eyes were greyish-green, green or hazel. However, this aid was not required by any blue-eyed subjects, and was used for only 2 per cent of those with greyish-blue or greenish-grey eyes, but it was required by 30 per cent of the subjects with light brown or brown eyes, and by more than 53 per cent of those whose eyes were dark brown.

My thanks are due to Sir Arthur Amies, and to the University of Melbourne Research Fund.

Development of the Aplacophorous Mollusc *Neomenia carinata* Tullberg

PRESENT-DAY authorities agree that, within the Mollusca, the chitons (or Polyplacophora) are closely related to the solenogastres (or Aplacophora). An important item influencing this view is the description, by Pruvot¹, of the development of seven overlapping, dorsal, plate-like spicules in the metamorphosing larva of the solenogastre, *Nematomenia banyulensis*. The appearance of these spicules has been considered to be a reminiscence of a chiton-like ancestor and, no doubt, has influenced many authors in coming to the conclusion that the solenogastres are degenerate chitons. Pruvot's description was based on observations on a single larva, but nonetheless the figure he gave of this developmental stage has been widely reproduced in general works.

The purpose of the present communication is to describe some observations on the development of *Neomenia carinata* Tullberg 1875, together with the work of Baba² on *Epimenia verrucosa*, they show clearly that, while the larva of *Nematomenia* may develop overlapping dorsal plates in the manner described by Pruvot, this is by no means the rule in the Aplacophora.

The embryos of *Neomenia carinata* hatch three days after oviposition (at 10° C) as trochophores with the blastopore still open abapically, but with no stomodaeum yet developed (Fig. 1A). These larvae swim over the bottom of the culture vessel, propelled by the strong cilia of the prototroch. As the larvae proceed, they spiral in the same direction as the metachronal waves travel around the prototroch (clockwise when viewed from the anterior). At 7-8 days metamorphosis begins, a caudal bud begins to protrude through what was formerly the blastopore (Fig. 1B). The tip of this bud bears a minute pore, the anus, and is ciliated. The rest of the bud, as it grows out, is unciliated but bears large numbers of pointed spicules (Fig. 1C). The 'trochophore' part of the larva remains ciliated, but becomes reduced in size, while the prototroch and apical tuft degenerate. The caudal bud comes to form by far the greater proportion of the larva (Fig. 1D). The last remains of the ciliated trochophore-mass are ingested through the mouth as the larva completes metamorphosis (Fig. 1E and F) and abandons pelagic life. At no time is there any trace of segmentation, nor of any dorsal shell-plates. When metamorphosis is complete the external surface of the body (except perhaps for the pedal groove) is unciliated, and the form is like that of the adult *Neomenia*.

This description is based on observations on large numbers of larvae of *Neomenia carinata* reared through metamorphosis in the laboratory, and the

Fig. 1. Metamorphosis of *Neomenia carinata* (camera lucida drawings of live larvae). A. Trochophore at 3 days, ventral aspect. B. Trochophore at 3 days, right lateral aspect. C. Trochophore at 10 days, right lateral aspect. D. Trochophore at 11 days, right lateral aspect. E. Newly metamorphosed stage (12 days), right lateral aspect. F. The same, ventral aspect. In E and F the spicules are not illustrated. The arrow shows the antero-posterior axis of the animals.

results so far obtained plainly show the need for a re-investigation of the development of *Neomenia*. At present, the indications are that the nearest relatives of the Aplousophora within the Mollusca may be found in the primitive Lamellibranchia rather than in the Polyplacophora. The resemblances in development between the solenogastres and members of the Brachopoda, Archannelida and Nemertea (to which various authors have directed attention) are probably without profound significance. The work on *Neomenia* is being continued and is financed by a grant from the Leverhulme Trust.

Dagger Nematodes associated with a Clover Sickness

Dagger nematodes (*Xiphinema* spp.) are now recognized as important crop pests in many North American states^{1,2} and occur widely in tropical countries³ in close association with plant roots. Because of their migratory ectoparasitic habit they are seldom observed feeding on the host plant, and where they appear to be associated with crop damage pathogenicity is difficult to prove.

Examination in early February of sickly white clover (*Trifolium repens* L.) plants from a clover ley near Crewkerne, Somerset showed no pathogenic organisms, but large numbers of dagger nematodes were recovered from the soil around the roots. The roots themselves bore minute lesions compatible with nematode feeding and many young rootlets

were brown and shrivelled at the tip. The field, a sandy loam, had been sown to grass and clover leys in sown out of the past ten years and had a similar early history.

The area was again sampled at the end of April, by which time the clover was dying off in patches. Many dagger nematodes were again recovered but fungal damage was also evident and small sclerotia believed to be those of *Sclerotinia trifoliorum* Erikss. were seen the stem eelworm *Ditylenchus dipsaci* Kuhn also occurred in numbers sufficient to constitute a possible cause of disease.

The exact role of dagger nematodes in this complex is thus uncertain, this is the first record of the genus *Xiphinema* in Great Britain, and observations and measurements suggest that the specimens recovered represent a new species, which will be described elsewhere.

Pollen of *Acacia* from Tufaceous Limestone near Udaipur

I HAVE undertaken the investigation of fossil microflora from a tufaceous limestone near Udaipur. This fossiliferous locality is about three quarters of a mile north west of the tenth milestone on the Udaipur-Gogunda Road. It was first described by Murti¹, who had suggested a tertiary age to these beds.

A few pieces of fossil were macerated with Schultz's solution and clear dehydrated mounts were prepared by passing the material through various grades of alcohol and mounting in Canada balsam. Some of the preparations were stained with safranin. The

Fig. 1. *Acacia* pollen grain (x 415)

slides so prepared showed many angiospermic pollen grains, some of which belong to the Leguminosae and the Gramineae. Also a few pteridophytic spores were observed.

One well-preserved pollen grain resembles very closely that of *Acacia longifolia*. It is a smooth compound 16-celled grain, eight cells are centrally placed, forming a sort of cubical block with the others arranged in a rectangular fashion. The central group is surrounded by eight peripheral cells all in a plane at right angles to, and bisecting, the central group. The peripheral cells are so placed that their eight contacts with each other are alternately opposite and midway between the four contacts of the central group. The group as a whole is flattened, with a more or less rounded outline, and the intersecting lines between the individual grains cross each other at right angles.

The exine is thick and its corners are rounded. The individual grains measure about 24.5μ in diameter and the whole compound grain is 69.5μ in diameter.

It is significant to note that fossil pollen grains of the *Acacia* type have been recently described from the Victorian Tertiary deposits, Australia, by Cookson².

I thank Dr. Chitley for her guidance in this work.

ARCHAEOLOGY

Stone Implements from Western Nigeria

RECENTLY a number of stone implements have been uncovered by labourers in sand quarries at Green Springs near Ibadan, Western Nigeria. These implements are associated with deposits of river sand and clay. The workmen wash the sand, discarding the clay and stones, usually placing the latter in heaps or scattering them about the ground. Thus it has not been possible to determine the level at which they were lying before excavation. Generally, however, the layers containing stone are between one and seven feet below the main surface-level.

Table 1 lists the definite artefacts found. The material is mainly quartz from the basement complex.

Polished stone axes are common in Nigeria, where they are often used as protective charms against thieves and thunder, in the belief that they are fallen thunderbolts. Flaked and tanged implements, however, have not previously been recorded from the Western Region of Nigeria, although flaked implements which have been compared to the Chelles-Le Moustier epoch in Europe are found in Northern Nigeria¹, and other flaked implements have been reported from the Eastern Region and the Cameroons². Typologically, the Green Springs

Table 1

| Description | Dimensions | No. |
|--|--|-----|
| Polished hand axes, Fig. 1 | Approx. $12 \times 6 \times 2\frac{1}{2}$ cm | 5 |
| Fragments | Average width 6 cm | 10 |
| Well-formed bifaced hand axe, Fig. 2 | $14 \times 0\frac{1}{2} \times 5$ cm | 1 |
| Unifaced hand axe, Fig. 3 | $23 \times 12\frac{1}{2} \times 4\frac{1}{2}$ cm | 1 |
| Polished cleaver-like stone, Fig. 4 | $7\frac{1}{2} \times 7 \times 3\frac{1}{2}$ cm | 1 |
| 'Points', Fig. 5 | Approx. $13 \times 0 \times 2\frac{1}{2}$ cm | 2 |
| Tanged unifaced blade, Fig. 6 | $11 \times 0 \times 2$ cm | 1 |
| Hand held polishing or grinding stones, Fig. 7 | Approx. $7 \times 6 \times 6$ cm | 3 |
| Bifacial discoid stones (scrappers?), Fig. 8 | Approx. $4 \times 0 \times 2$ cm | 2 |
| Anvil stones indented both surfaces, Fig. 9 | Approx. $0 \times 7 \times 4$ cm | 4 |
| Balls | 5-8 cm dia | 15 |
| Eccentrically perforated stone, Fig. 10 | Width, 8 cm, perf., 2 cm | 1 |
| Fractured stone cylinder | 6 cm dia | 1 |

implements fall into two groups: (a) neolithic types, represented by stone balls, polished axes, anvils and grinding stones, and (b) palaeolithic types, represented by the points, the flaked axes and the tanged blade. The latter are suggestive of the Aterian cultures of North Africa^{3,4}.

We are of the opinion that systematic excavation in the area may be of advantage to pre-history. We wish to acknowledge the kind help of Mr. R. Hockey, geologist, Geological Survey Department, Federal Government of Nigeria.

Monday, August 31—Saturday, September 5

10TH CONGRESS OF THE INTERNATIONAL ASTRONAUTICAL FEDERATION (at Church House Westminster London S W 1)

Wednesday, September 2—Wednesday, September 9

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (at York)—Annual Meeting

Wednesday September 2

At 8 p.m.—Sir James Gray O.B.E. M.C., F.R.S. "The Proper Study of Mankind is Man" (Presidential Address)

Thursday September 3

At 10 a.m.—Prof. L. P. Bates, F.R.S. "The Visualization of Magnetic Processes" (Presidential Address Section A)

At 10 a.m.—Prof. M. Stacey, F.R.S. "Medical Applications of Complex Carbohydrates" (Presidential Address Section D)

At 10 a.m.—Dr L. Harrison Matthews, F.R.S. "Man and the World Fauna" (Presidential Address Section D)

At 10 a.m.—The late Dr W. R. G. Atkins F.R.S. "Plants on Land and in the Oceans" (Presidential Address Section K read by Dr G. P. Spencer)

At 10 a.m.—Dr H. G. Sanders "Balance in British Farming" (Presidential Address Section M)

At 11.15 a.m.—Mr W. B. Day "The Influence of Pathogenic Factors within the Rooting system on the Development of Even-aged Plantations" (Chairman's Address Section K*)

At 11.30 a.m.—Sir Ewart Smith, F.R.S. "The Critical Importance of Communication and Transport" (Presidential Address Section G)

At 2.30 p.m.—The Countess of Albemarle "Living with Science" (Presidential Address Section X)

Friday September 4

At 10 a.m.—Prof. K. G. Edwards "Trends in Urban Expansion" (Presidential Address Section E)

At 10 a.m.—Prof. John Jewkes "How Much Science?" (Presidential Address Section F)

At 10 a.m.—Sir James J. Robertson "What Are Our Schools For?" (Presidential Address Section L)

At 11.30 a.m.—Prof. Magdalen Vernooy "Perception Attention and Consciousness" (Presidential Address Section J)

At 8 p.m.—Prof. M. Swann "The Uneaten Pattern of Growth" (Evening Discourse)

Sunday September 6

At 10.30 a.m.—Official Service at York Minster Preacher: The Most Reverend The Lord Archbishop of York.

Monday September 7

At 10 a.m.—Prof. G. M. B. Balman F.R.S. "Recent Developments and Trends in Palaeontology" (Presidential Address Section C)

At 10 a.m.—Prof. Ian A. Richmond "The Nature and Scope of Archaeology" (Presidential Address Section H)

At 10 a.m.—Prof. A. Homology "Artificial Organs—Biological Applications" (Presidential Address Section I)

At 8 p.m.—Sir William Hildred "International Air Transport Problems" (Evening Discourse)

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ANALYST (qualified for general inorganic analysis) to the Houldsworth School of Applied Science mainly for work on silicates—The Registrar The University of Leeds (2 August 59)

LECTURER IN MATHEMATICS—SENIOR TUTORS (2) IN GEOGRAPHY and LECTURERS (2) IN EDUCATION at Palmerston North University College (Victoria University of Wellington), New Zealand—The Secretary Association of Universities of the British Commonwealth 36 Gordon Square London W.C.1 (New Zealand August 31)

LECTURER (preferably with experience in solid state or low level physics or ultrasonics) IN PHYSICS—The Registrar Queen Mary College, Mile End Road, London E.1 (August 31)

ASSISTANT LECTURER (preferably with interests in plant physiology and plant ecology) IN BOTANY—The Principal Royal Holloway College (University of London) Englefield Green Surrey (September 1)

SENIOR LECTURER AND DIRECTOR (with high academic qualifications and experience of high-speed digital computers) OF THE DEPARTMENT OF COMPUTATION—The Secretary and Registrar The University of Southampton (September 1)

ASSISTANT LECTURER OR LECTURER IN THE DEPARTMENT OF AGRICULTURAL ECONOMICS—The Registrar University College of Wales Aberystwyth (September 1)

LABORATORY ASSISTANT IN THE DEPARTMENT OF BOTANY—The Registrar University College Singleton Park Swansea (September 8)

LECTURER IN ZOOLOGY to the University of Queensland Australia—The Secretary Association of Universities of the British Commonwealth 36 Gordon Square London W.C.1 (Australia September 11)

ASSISTANT LECTURER IN DARTING—The Registrar University College of Wales Aberystwyth (September 12)

LECTURER IN PURE MATHEMATICS SENIOR TUTORS (2) IN PURE MATHEMATICS and a SENIOR LECTURER IN PHYSICAL METALLURGY at the University of Sydney Australia—The Secretary Association of Universities of the British Commonwealth 36 Gordon Square London W.C.1 (Australia September 19)

LECTURERS (2) IN ASTRONOMY in St. Salvator's College University of St. Andrews—Joint Clerk to the University Court College Gate St. Andrews (September 19)

LECTURER IN EDUCATION at the University of Otago Dunedin New Zealand—The Secretary Association of Universities of the British Commonwealth 36 Gordon Square London W.C.1 (New Zealand September 20)

SENIOR TUTOR DEMONSTRATORS (2) IN ZOOLOGY at the University of Sydney Australia—The Secretary Association of Universities of the British Commonwealth 36 Gordon Square London W.C.1 (Australia September 26)

LECTURER IN MATHEMATICS at the University of New England Australia—The Secretary Association of Universities of the British Commonwealth 36 Gordon Square London W.C.1 (Australia September 28)

LECTURER IN GEOGRAPHY at the University of Sydney Australia—The Secretary Association of Universities of the British Commonwealth 36 Gordon Square London W.C.1 (Australia October 1)

MYCOLOGIST (with a good honours degree in botany with mycology as a special subject) a knowledge of the more fundamental aspects of animal and human mycoses and preferably a knowledge of Latin and other languages) at the Commonwealth Mycological Institute Kew—The Secretary Commonwealth Agricultural Bureaux Farnham House Farnham Royal Bucks (November 30)

JUNIOR PLANT BREEDER (male with a good honours degree in botany with postgraduate experience in the technique of plant improvement) at the West African Cocoa Research Institute (serving initially at Tafo Ghana) to carry out research on plant breeding problems relating to cocoa—The Director of Recruitment Colonial Office London W 4 W 1 quoting BOD 197/200/98/T

LECTURER IN PHYSICS and an ASSISTANT LECTURER IN PHYSICS (Grade B*)—The Clerk to the Governors Northern Polytechnic Holloway London N 7

SENIOR LECTURER IN ZOOLOGY—The Registrar Bradford Institute of Technology Bradford 7

TECHNICIAN IN THE ZOOLOGY DEPARTMENT—The Secretary Royal Holloway College Englefield Green Surrey

government and the public. All that he writes, however, about the futility of the pathological secretiveness of the British Government, matched in Europe only in Spain and Portugal, applies even more forcefully where science is concerned. These attempts at secrecy merely hinder scientific or technical advance without promoting security and, more serious, impede the informed public discussion and understanding of what both science and Government are doing which is essential if science is to be wisely used.

This is even more important now that we stand at the cross-roads, as Sir Solly reminds us. Hitherto, we could claim that the applications of science have increased the sum total of human happiness. The process of applying scientific knowledge is as endless as is the prospect of getting new knowledge, and we can be reasonably certain that neither the backward and under-developed nor the rich nations will allow the process of applying the fruits of scientific knowledge to stop, either in the national or the international framework. In this process, however, means become ends, because as new ways of doing things are discovered, they transform the things done, and so their purpose. In fact, weapons may end by determining strategy and even the purpose behind the strategy.

Here, in Sir Solly's view, arises the real clash to-day between the scientist and the humanist, and this form of scientific application could indeed constrain our democratic liberties and even, if we ceased to be vigilant, the liberty of science itself. That would seem to imply a special responsibility for the scientist, though Sir Solly does not agree that such a responsibility means more than that the scientist is better able to appreciate scientific facts. It is not reasonable, he points out, to expect the scientist as such, who is not responsible for the application, to accept the responsibility for predicting some vast social transformation which might result from a seemingly innocent observation.

Nor is that all, for it has to be remembered that the process of government involves much more than taking account of scientific and technical factors and their implications. Even if the problem is essentially a scientific one, the statesman or minister who has to take a decision and formulate a policy must have regard to public acceptability, and accordingly to the public understanding. Normally there will be many other factors to be considered, and it is the corollaries of the application of science that are of importance, since they are most readily appreciated and most relevant politically.

In this connexion Sir Solly reaches the same conclusion as to the importance of the views of Dr Chapman and the recent book by Mr C H

constituting to-day an essential part of an education in the humanities. An understanding of social and political purpose can no longer be realized through the liberal arts, unless their scope is widened to embrace a proper understanding of the scientific knowledge the application of which is so rapidly transforming our intellectual and material environment.

It is with realism and not arrogance that Sir Solly places science, technology and humanism in that order of importance in determining our affairs, and in the same spirit that he suggests that, to continue as a potent educational discipline, the humanities must encompass an understanding of the social forces which arise from the application of the natural sciences. Nor does he suggest that higher education necessarily guarantees higher virtue or higher political wisdom, rather we are likely to avoid bad decisions if we realize that decisions taken in major scientific matters to day may determine the course of the future. Dr Chapman comments that no other European country has emphasized to the same extent as Britain the strange division between science and the humanities, with the result that the common difficulty of finding adequate numbers of Civil servants with sufficient specialized training is accentuated, nevertheless, he recognizes that all branches of the public service, ministries as well as industrial public enterprises, need a proper balance between administrator, manager and technician, and that ministries often lack technical competence in scientific, industrial and economic fields.

Apart, however, from referring to the way in which France has been able to meet some 90 per cent of her requirements for first-class engineers and technologists with administrative experience, Dr Chapman does not discuss the place of the scientist or technologist in administration. He stresses the importance of education and recognizes that this means the education of the general public as well as of the administrator, and the politician and minister. He makes the significant comment that a menial mind should not be a qualification for high administrative office, but his constructive criticism is rather on the structure of the Civil Service itself, where it points to the fresh thinking that is required in order that the public services may be able to fulfil the needs of the modern State.

Nor are his suggestions for the Civil servant or the minister alone. They are no less worthy of the attention of professional organizations, for they point to ways in which not merely could the public services be absorbed more effectively into the structure of the modern State, but also, and no less important, the professional scientist or technologist could serve the State under conditions less likely to constrain professional ideas and tradition. Mr C H

in "The Spirit of British Administration", is as to the possibility of a general education. He believes just as firmly as Sir Dr Chapman that the survival of general education is of parliamentary

government or indeed of any government based on a discussion, with this goes the survival of administrators who are not daunted by specialists take it for granted that the practical implications of all their work can be explored and explained in a sufficiently agile lay mind

The defence of freedom is a central problem of our age, and it is not simply one of defence against aggression from totalitarian systems outside. Sir Lionel Zuckerman shows clearly how it arises from the nature of science itself, and from the impact of science on society. Any scientist or technologist who is concerned about these changes and how they can be best avoided or minimized will be led inevitably to think not simply about the association of scientist and technologist with government but about the process of government itself. To such thinking both the books mentioned above offer some contribution in different ways: they can assist in the understanding of the nature of administration and the limitations within which the administrator works; they indicate also the mind of the administrator and how it is trained or formed, and they point to some of the ways in which reform or developments are required if the task of government is to be discharged adequately to-day. But, like Sir Lionel Zuckerman's volumes, they are primarily a challenge to the scientist or technologist to accept such responsibility to-day, and a stimulus to the creative thought by which alone that responsibility can be discharged.

THE NEED FOR MARINE RESEARCH

Living Resources of the Sea

Opportunities for Research and Expansion. By Dr Lionel A. Walford (A Conservation Foundation Study). Pp xv+321 (New York: The Ronald Press Company, 1958). 6 dollars.

It is more than sixty years since the foundation of the International Council for the Exploration of the Sea, the avowed purpose of which is the accumulation of knowledge necessary for the rational exploitation of marine resources in northern waters. There are now a dozen or more councils or commissions covering other areas of the world, including commissions limited to certain animals, such as halibut, salmon, tuna and whales. The fear of over fishing, which has been the spur to the activity of the International Council for the Halibut Commission and other more recently formed organizations, has always been well to the fore in the minds of those concerned with the science of the sea. The necessary research has been concentrated on the main northern fisheries, but now the demand to feed the under-nourished millions has focused attention on the sea as a whole as a possible source of protein.

At the request of the Conservation Foundation, Dr Lionel A. Walford, chief of the Biology Branch of the U.S. Fish and Wildlife Service, was asked to explore the question "What scientific researches, apart from those which are in progress, would contribute significantly toward learning how to enlarge the yield of food from the sea in answer to human needs?" This has resulted in a useful book in which

Dr Walford considers the problem from human and biological angles. The major conclusion is that research must be extended into those areas where the need is greatest, and where there is the most possibility of increasing the food supply where it is most lacking. A number of interesting charts are included indicating the existing intensity of fishing and research in different parts of the world, those areas of the sea which might be expected to be productive, and those on land where the need for food is greatest. This survey impresses on us that where the fisheries are at present most developed and exploited there lies the major effort of research. The number of pertinent marine laboratories is now about 240. Nearly 90 per cent of these are in the northern hemisphere and 85 per cent north of latitude 20° N. Thus, those areas in which the need for research is now greatest have least facilities to do so both in material equipment and trained personnel. The problem is one both of research and development, and it is not easy to do the former without the latter unless exploration for fishing grounds is subsidized by governments.

It is thus both humanely and politically advisable that the countries most advanced in marine research should do their utmost to help the under-developed areas. Since the Second World War fisheries research under the auspices of Her Majesty's Colonial Office has added significantly to knowledge in certain areas, the U.S. Fish and Wildlife Service has extended its investigations into the oceanic pelagic fisheries, and the United Nations Food and Agriculture Organization has helped in supplying experts and supervising training. But this effort should if possible be much increased, and every encouragement given to those who wish to do research that will add to our knowledge of conditions in tropical seas.

Dr Walford's book is not a text-book; it attempts to show where be the gaps in knowledge, and these are both large and numerous. As a single example of what we know of the probably enormous food potentialities available in pelagic cephalopods which now constitute 60 per cent of the Japanese fisheries?

Marine resources are also not necessarily all of value as food; some may have medical value. On our own planet there lies a whole world which we have only recently begun to study extensively. It is to be hoped that Dr Walford's book may stimulate us to greater efforts.

F. S. RUSSELL

ANOTHER DEBT TO DARWIN

Index Kewensis

Plantarum Phanerogamarum Supplementum Duo decimum Nomina et Synonyma Ornium Generum et Specierum ab Initio Anni MDCCCLXI usque ad Finem Anni MDCCCLV. Nonnulla etiam antea Edita Complectens Ductu et Consilio Georgii Taylor confecerunt Herbarii Horti Regii Botanici Kewensis Curatores. Pp iii+157 (Oxonii: E. Pello Clarendon domano 1959). 75s net.

IN this centenary year of the publication of the "Origin of Species" biologists owe very much in mind the debt that they owe to Charles Darwin. It is probable, nevertheless, that many of them do not remember that the inception of "Index Kewensis" was due not only to Darwin's perception of the necessity for such a work but also to his generosity in providing the funds.

We might at this moment remember that the work was started under the supervision of Darwin's great friend, J. D. Hooker, and has since been supervised by subsequent directors of Kew and carried out by numerous able, but often anonymous, helpers.

"Index Kewensis" is taken so much for granted by plant taxonomists working with angiosperms that it is often not fully appreciated. To anyone who has struggled, even briefly, with taxonomic and nomenclatural problems in groups such as algae, where no such index exists, the lack of it is keenly felt and the value of a catalogue of names with places of publication is soon fully realized. It is interesting to note in this connexion that an "Index Muscorum" is due to be published shortly—another descendant of the original Darwinian idea.

"Index Kewensis", the twelfth quinquennial supplement to which has now been published under the direction of Dr. G. Taylor, supplies far more information about flowering plants and papers concerning them than might at first sight appear.

For example, in the five-year period between 1951 and 1955 approximately 12,000 species of flowering plants have been described. This, after more than two centuries of taxonomic work in the post-Linnean period, is a staggering total and gives some measure of the imperfection of our knowledge of the dominant group of plants.

It is also easy to obtain from these Supplements references to important monographs and information about the geographical areas and the plant groups which have been the subject of special attention in the recent past, as well as the names of the workers concerned.

In conclusion, I may perhaps be allowed to repeat what has so often been said before: "Index Kewensis" is indispensable. T. G. TUTIN

OPTICS: CLASSICAL AND MODERN

Concepts of Classical Optics

By Dr. John Strong. Pp. xxii + 692. (San Francisco: W. H. Freeman and Company, London: Bailey Bros. and Swinfen, Ltd., 1958.) 9.50 dollars, 80s.

THIS is a very good book, and one of its best features is the care taken by the author to ensure that the student understands what is going on. Mathematical treatment is kept to a minimum, but where it is necessary we are not left to flounder; the author explains what he is doing by means of a sort of running commentary, and even reassures us that although the solution we are after is buried in complication at the moment it is going to emerge safely in a minute. The only criticism here is that some simplification of the symbols used would lead to even greater clarity; for example, why was it necessary to use the symbol λ for mass early in Chapter 1, only to announce, a few pages later, that "we now abandon this for its customary use, symbolizing wavelength"?

The author also takes the trouble to expose and explain theoretical difficulties which are too often ignored. A good example of this is the section on "No Diffraction, by Cornu's Spiral", in which the limitations of this construction are pointed out, with the conclusion that "it affords the student an example of a typical theory in physics which has an impressive neatness, inspiring awe, which makes

necessary compromises, requiring prudence, while is blennished by a lack of complete validity, requiring understanding."

At first glance the most distinctive feature of the book is the character of the illustrations. These at once in the style one associates with the author's well-known book on laboratory practice. They have a freehand appearance, are pleasant to look at and are extremely clear; for example, the drawings in the section on double refraction, which is inherently a difficult subject to illustrate, are models of clarity. What is even more important is that the drawings showing apparatus give one a good idea as to how it is actually constructed—too often one's first sight of the actual equipment comes as a shock after having seen only text-book illustrations. It is only in some of the attempts to reproduce optical images by means of sketches that actual photographs might have been better.

The book is described in the preface as being intended for an intermediate course in optics, taking one or two terms. This is a considerable understatement of the ground covered and the book should be valuable for much more advanced students and also for general reference purposes. It in fact covers most of the physical optics required for an honours degree in physics.

The only real adverse criticism of this book concerns the price—£4—which is surely at least twice as much as most students would willingly pay for a single book. This is to some extent offset by the seventeen so-called appendices, which occupy nearly half the book and are in effect a series of short monographs by specialists. To quote the preface: "these are intended to give the student the flavour of current activities and interests in our field." The topics covered in this way include, among other things, interferometer apodization, Fourier transformations and interferometric spectroscopy, radiation detectors, micro-wave optics, wave theory of image formation, lens design, fibre optics and filters. One of the appendices supplies some of the mathematical background assumed in the rest of the book. This is well done, and includes frequent attempts to make the student think—both by formal examples and by interjected questions such as "(why?)" or "(how do we know?)" after mathematical steps in the text. J. E. GEAKE

BLOOD GROUP METHODS AND TECHNIQUES

Practical Blood Grouping

By Dr. F. Stratton and Dr. P. H. Renton. Pp. xxiv + 331 + 16 plates. (Oxford: Blackwell Scientific Publications, Springfield, Ill.: Charles C. Thomas Publisher, 1958.) 42s. net.

OVER the past fifteen years mass grouping of blood donors and ante-natal cases has grown enormously, and of necessity special methods and techniques have been evolved to meet an entirely new situation.

The authors of this book, faced with the alternative of describing a multiplicity of methods, or confining themselves to those known and well tried in their own laboratory, have wisely chosen the latter.

Not all would agree that the paper slide test offers substantial advantages over existing (and equally well-tried) techniques, for example, tube testing. Even if some small advantage could be

demonstrated, the disorganization which would follow a drastic change to a new technique would carry inherent dangers, probably outweighing any benefits likely to result.

Nevertheless it is always of value to study methods which have proved satisfactory over a number of years, and many pathologists engaged in this work will be most interested in a method which has satisfied such critical observers as the writers.

In the section dealing with ante natal grouping, the possible alternative to the current practice of ABO and Rh(D) screening with the customary follow up of the Rh(D) negatives is attractive from the point of view of economy in laboratory working. It might, however, be difficult to convince clinicians, and particularly obstetricians, that this economy at the expense of their advance knowledge of their patients' groups would be justified. It is certain that they would argue as is foreseen by the authors, that obstetric emergencies would not be so well covered.

It would seem that the writers themselves have not adopted this possible alternative in their own practice, having doubtless explored the possibilities and the difficulties which it would entail.

An interesting and informative chapter on cross matching difficulties encountered in their own laboratory (p. 337) was found to be slightly confusing. For example, of the 2,967 cases involved the donor's blood was not of the ABO group as stated on the bottle in two cases.

Without knowing the total number from which the 2,967 are selected the two wrongly labelled bottles may or may not represent a much higher proportion of error than is considered unavoidable in an earlier chapter.

In any event some explanation of how these two bottles escaped the rigid checks and cross-checks, described in detail in Chapter 7 where the combined manipulative and serological sources of error are calculated at 1 in 43,000, would be helpful.

Two mistakes of this nature, picked up on cross match might represent a total of four such errors in the series, since bottles wrongly labelled O would escape detection by this final cross matching check.

Minor points, such as these, and the confusion in the description of the anti U antibody (p. 381) must not be allowed to detract from the value of this book. The subsequent editions, which will assuredly be demanded, will provide opportunity for elucidation and correction.

The bibliography is comprehensive and indicates the degree of care that has been taken in providing a manual which should appeal to pathologists, technicians and indeed to all engaged in blood transfusion work.

R. A. ZEITLIN

SCIENCE AND THE HUMANITIES

History and Philosophy of Science

An Introduction By L. W. H. Hull Pp xi+340+16 plates (London and New York Longmans, Green and Co., Ltd., 1958) 25s net

THIS is not a detailed history of science. It tries to bridge the gap between science and the humanities by considering scientific ideas in a context of history and philosophy. In these words the author describes the object of his work. Few will deny the existence of the gap, or the need to bridge it and a book of this nature should be welcomed, on

one hand by those whose training and background have led to an emphasis on technology and on the other, by students of the humanities who seek to understand the vital contribution of science to human thought. The general reader also will find the author's approach both interesting and stimulating. He anticipates the criticism that "most readers will, no doubt, find too little about some topics and too much about others". He points out that before the spread of evolutionary ideas the influence of biology seems scarcely comparable with that of mathematics and the physical sciences.

The book opens with a review of ancient science covering three periods: the first from the beginnings of science until the rise of Athens after the Persian wars, the second until the Macedonian conquests of the fourth century B.C., the third period takes the Alexandrians as its theme. This review is comprehensive in relation to the hundred pages allotted to it, and makes interesting and instructive reading. Chapter 4 carries the story through the period of the Middle Ages with some reference to Arabic contributions.

In the two following chapters celestial geometry and celestial mechanics are very adequately surveyed from the time of Copernicus to that of Newton. With such fundamental changes in ideas concerning the universe it is appropriate that a chapter is devoted to Changes of Outlook and Method and this constitutes one of the most valuable parts of the book. A separate chapter deals with other scientific developments in the sixteenth and seventeenth centuries, such as the phenomenon of light and attention is directed to the philosophical thought of Berkeley and Hume.

The chapter 'The Nineteenth Century and Evolution' introduces the reader not only to Darwinian theory and its implications but also to its significance in the development of thought. In an 'Epilogue' which includes the theme of twentieth century trends the author gives a warning which it is to be hoped in the interests of both science and the humanities will not fall on deaf ears. 'It is urgently necessary to restore the unity of intellectual life. Unless we do so we shall soon lose what is best in Western civilization.'

H. D. ANTTONI

INDIAN PREHISTORY

The Pre-historic Background of Indian Culture

By D. H. Gordon (Sponsored by Bhulabhai Memorial Institute) Pp xi+190+32 plates (Bombay M. D. Desai 1958) Distributed by N. M. Tripathi (Private) Ltd., 1958) Rs 20

UNTIL recent years the study of the archaeology of the Indian peninsula has woefully lagged behind that of some other parts of the world. Especially is this so in the case of its prehistory. It is true that isolated finds of stone implements have been made from time to time during the past one hundred years—and in this connexion the name of Bruce Foote in Madras has an honoured place—but it is only recently that it has become possible to piece together an overall picture of the successive cultural phases in India and even now the gaps in our knowledge are more than numerous. The subject is complicated since India seldom presented a uniform picture. Even in very early times the Madras area formed part of the vast Chellean-Acheulean complex

while the northern regions belonged to another and distinct province which included the early stone-age cultures of Burma and south-east Asia. Most of the worthwhile investigations have, until recently, been undertaken by non-Indians, but nowadays highly trained investigators like Dr Sankalia and his colleagues have come into the field and are making important explorations. But there is so much to be done in the field that there is little opportunity for these investigators to stand back, as it were, and give a general report of what has so far been pieced together of the ancient history of their fascinating land. It is here that Colonel Gordon steps in.

Gordon has served, travelled and explored in India for thirty-two years and himself has undertaken not a few investigations, and he knows as much about the rock-shelter paintings of the Central Provinces as any man alive. But in the volume under review he has set himself the task of attempting to see the archaeology of India as a whole and to make available for students the latest ideas on the subject. Geographically, India is a large and varied country, and just as the cultures are not, and never have been, uniform throughout, so the climate differs in different areas and has differed greatly in past ages. A brief study of climate changes must necessarily be considered first, and then the earliest stone age cultures can come under review. The later stone age cultures are next dealt with, and here it must not be forgotten that in some regions these seem to have continued until quite a late date, indeed some of the Megalithic tombs and polished stone axes have been dated as late as the third century B.C. A chapter on the peasant potters of Makran, Baluchistan and Sind follows, and this naturally leads on to a discussion of the civilization of the Indus valley. Thanks to Sir John Marshall's work and the excavations at Mohenjo-Daro and other sites, a great deal has come to light of recent years, and this fascinating civilization has become comparatively well known. The period of invasions and the rock paintings and engravings are then dealt with, and in conclusion there are chapters on the 'Dark Age' stone and copper cultures, leading to a chapter which carries on the story to the threshold of history and to the use of iron.

Colonel Gordon has done his job well. It must not be expected that in one small volume the student will find detailed studies of the archaeology of the whole of India. But the selections made are judicious and the result does give a connected picture of the past. There are a number of full-page illustrations at the end of the volume and plenty of maps, tables and text figures.

M. C. BURKITT

FLUID SYSTEMS

Chemical Engineering Practice

Edited by Herbert W. Cremer and Trevor Davies
Vol. 6 Fluid Systems II Pp. vii + 600 + xx
(London: Butterworths Scientific Publications,
New York: Academic Press, Inc., 1958) 95s,
13 30 dollars

THE latest volume in this series covers a very wide range of chemical engineering operations, although for convenience the editors have labelled the volume "Fluid Systems II". There are fifteen chapters covering gas absorption, fluidization, liquefaction and fractionation of gases, adsorption, leaching, crystallization, colloids, filtration, sublimation and the practice of evaporation. Dr Norman and his

colleagues from Manchester have written two chapters on the principles of gas absorption and the characteristics of packed-column absorption towers. The first chapter is excellent, not only for these in universities and technical colleges but also for all who are concerned with gas absorption. The second chapter, though good, lacks a little of the practical touch one would have liked. The chapter on evaporation practice by Mr Watkins from King's College, London, assisted by Mr Macmurray from Scott and Son and Mr Forker from the Dupont Company, is very readable and covers the usual types of units. More attention might have been given to the actual size of units and some of the practical problems associated with operating evaporators would have been appreciated.

The chapters on fluidization by Dr Botterell from Birmingham and Mr Turner from British Petroleum are excellent, and will be looked at very much as indicating the position with this relatively new technique, which offers so much promise of further development. In the same way the chapters by Dr Gardner of British Oxygen Co., Ltd., and by Mr Pasteur of J. and E. Hall are welcomed as showing the real problems and successes of low-temperature technology. Low-temperature gas separation is still a new technique but most challenging as a technical process.

Prof. Donald has given an interesting account of leaching, including one or two references to history which are lacking from the other chapters. One is left with the idea that operations of such long standing are not yet carried out with very elegant equipment and there must be room for improvement here. The chapter on the principles of filtration is also written by Prof. Donald.

Dr Mullin from University College, London, has written the chapters on crystallization, centrifuges, and colloid science. These are all difficult subjects and one would certainly have liked more on the practical difficulties of continuous crystallizers. We cannot learn from these chapters the physical size of units for definite capacities and there are many unresolved problems in the production of true regular crystals.

Mr Salter, from Dorr-Oliver, and Mr Hosking, from L. A. Mitchell, have given a clear statement of the variety of filters and the method of selection of equipment. Their section on accessories such as pumps and blowers for vacuum filters is a real attempt to size up these important auxiliaries. One cannot help feeling that some of these units have had their day and are a bit crude, some pruning of variety might have been suggested by these specialized authors.

This book enables one to see the range of processing problems which are now regarded as the province of the chemical engineer. It is not surprising that in his relatively short history there are many untidy edges to his work. Apart from selecting the right type of unit there is a definite degree of uncertainty as to the ability of the engineer to scale-up such plant satisfactorily.

The book will be welcomed particularly as it provides a discussion of the work in quite a number of fields which have not been adequately covered before in the British literature.

Mr Cremer has written a foreword to the volume in which he refers to the untimely death of the former managing editor, Mr Trevor Davies. Mr S. B. Watkins, head of the Chemical Engineering Department at King's College, London, has taken up the work.

J. M. COULSON

Basic Electricity

(A Course of Training Developed for the United States Navy by Van Valkenburgh, Noogor and Novillo, Inc. Adapted to British and Commonwealth Usage by a Special Electronics Training Investigation Team of the Royal Electrical and Mechanical Engineers) Part 1: Pp vi+127 Part 2 Pp vi+121 Part 3 Pp vi+122 Part 4 Pp vi+104 Part 5 Pp vi+117 (New York: The Boleat Press, London: Technical Press, Ltd., 1959) 12s 6d net per part 55s not the set

THIS five part course, aimed at training technicians rather than electrical engineers is distinguished by the simple language of its text and its concentration on essentials. It is illustrated to an extent that makes it (or at least the first two parts of it) qualify as a visual aid as well as a text-book. The cartoon like artistry is a little florid—the sort of thing one might associate with 'Jane' but not with 'Fighting Ships' and the going seems slow, by ordinary teaching standards, in the early stages. It soon becomes evident what the authors are up to—using the same technique as the creators of the La'l Abnors and the purveyors of branded goods, to set up an image and attract a loyalty to it, the image being that of the electron. I have no doubt that the early parts would be highly successful in bringing people who would not normally gain a great deal from the printed word to a really sound understanding of the fundamental principles, and simple circuits and meters. The last three parts use the artist in a much more quantitative kind of way. The usual work on alternating current, a.c. circuits and electrical machinery is done with the minimum of algebra; but every important result is explained and illustrated with the help of vector diagrams and graphs. These parts, in fact are a very well-conceived textbook of the orthodox type, and contain some new ideas for expounding the more difficult points, which are never skirted. Instructions for experiments are given, with a list of apparatus needed to work through them. The really exacting part of instruction at this level is in making the initial contact with the pupil. The originality and skill that have been lavished on the early stages of the course should ensure for it a very high contact potential. G. R. NOAKES

The Strategy of Chemotherapy

Eighth Symposium of the Society for General Microbiology, held at the Royal Institution, London April, 1958. Edited by S. T. Cowan and E. Rowatt. Pp ix+360 (Cambridge: At the University Press, 1958. Published for the Society for General Microbiology) 35s net

THIS symposium shows what a complex field of research has developed from Ehrlich's pioneer work on the use of specific substances to attack micro-organisms in the tissues without damage to the host. The organizer invited contributors to suggest fresh methods of attack and the result was a series of papers of extreme diversity in approach, techniques and objectives. They were given by the micro-biologist, the pharmacologist, the biochemist and physical chemist, and include such fundamental conceptions as membrane penetration, bacterial cell wall synthesis and energy supplying reactions wherein the research worker is endeavouring to discover some subtle difference in the components of host and parasite which may be exploited to the detriment of the latter. At the other end of the scale

are the frankly empirical mass methods used so successfully in the production of the antibiotics and other synthetic drugs, but without any fundamental explanation. These random methods still offer probably the greatest chance for further production of new compounds and therefore have their place in the field of chemotherapy, but the symposium does emphasize the necessity for the combined operations of each type of research worker if chemotherapy is to have a logical basis of development and not be, as one worker defined it, dependent upon intelligent guesswork. H. BERNY

The Native Pinewoods of Scotland

By Prof. H. M. Stoven and A. Carlisle. Pp xvi+368+20 plates (Edinburgh and London: Oliver and Boyd, Ltd., 1959) 63s net

THIS beautifully produced book will be a welcome occupant of the bookshelves of many students of Scottish history and natural history. The subject-matter is both broader and narrower than the title might suggest—broader in so far as the authors discuss much relating to the general history of Scottish forests and to the relationships of pinewoods to woodland of other species, narrower in so far as some features of the pinewoods receive particularly detailed treatment.

The authors trace the history of Scottish woodlands from the Pleistocene period onward through historic times, collating and summarizing an immense amount of evidence from geological, palynological and archaeo-logical sources which has never before been brought together. They pass on via a very general ecological account of the pinewoods to a systematic description of all the known surviving examples of woods which are with reasonable certainty composed of naturally regenerated indigenous pine. Carefully prepared maps accompany the descriptions, and show the exact distribution of pine and of other species of trees in the neighbourhood of the pinewoods. This portion of the book is noteworthy for copious historical information which has been gathered together from estate records, early maps, accounts by travellers, etc. An account of Dr Carlisle's study of the morphological variation of pine in Scotland concludes the book.

A fine series of photographs illustrate the book. I have noticed only one trivial misprint. The book should form a valuable foundation for further ecological work in our western outposts of the European boreal conifer forest which have so long attracted British naturalists. E. W. JONES

South African Animal Life

Results of the Lund University Expedition in 1950-1951, Vol. 5. Edited by Bertil Hünström, Per Brännö and Gustaf Rudebeck. Pp 520 (Stockholm: Almqvist and Wiksell 1958) 75 Sw kr

VOLUME 5 of this series of publications contains accounts on Porifera, Crustacea, Diplopoda, Diptera, Homoptera and Coleoptera. Six chapters each on the Homoptera and Coleoptera make up the bulk of this volume. As in earlier volumes the taxonomic treatment is amplified by zoogeographical accounts, and frequently the general accounts are not restricted to the description of the Lund collections, but bring them into relationship with other material. For an assessment of the scope and general merit of this series the reader is referred to an earlier article in this journal (*Nature* 180, 56, 1957).

Inside the Living Cell

Some Secrets of Life By Dr J A V Butler Pp 174+16 plates (London George Allen and Unwin, Ltd, 1959) 21s net

DR J A V BUTLER'S former book, "Man is a Microcosm", was reviewed enthusiastically in these pages some years ago. The scope of the present work is much wider, quite apart from the fact that many parts of the subject have advanced radically in the past few years.

The author describes in straightforward language many of the great advances which have been made during the past ten years in our knowledge of the mechanisms which operate within living cells. These include not only the ways in which food materials are taken and transformed into proteins, nucleic acids and other constituents, but also the way in which the ability to make all these is transmitted from generation to generation. In these processes we come very near to the basic mechanisms of life itself. In addition to his excellent account of the normal behaviour of cells the author discusses neoplasms and other abnormalities caused by ionizing radiations, those which seem to occur spontaneously and those which are caused by chemical carcinogens.

Later in the book some abilities of specialized cells, such as those which form muscles and nerves, are dealt with, and an account is given of the immense structures which living cells achieve in the higher animals and finally in man.

Altogether the reader is given some idea of what life has achieved, first, in reaching the level of the cell, and secondly, in elaborating great assemblies of cells in the higher forms of life. Finally, the author discusses the causes and significances of ageing and death, and the meaning of life in the world of atoms.

Throughout, the work is informed by the original work and thought of the author. The book is beautifully produced in every way. The illustrations are particularly good and include photomicrographs such as those by D A Sholl of nerve cells in the visual cortex, and by R W G Wyckoff of bacteriophage. The book can be recommended warmly to many classes of reader. Most of it should appeal to the educated adult and it will be invaluable for the general reading of a good science sixth former, or university undergraduate.

W L SUMNER

Organic Syntheses

An Annual publication of Satisfactory Methods for the Preparation of Organic Chemicals, Vol 37, 1957 Edited by James Cason Pp vii + 109 Vol 38, 1958 Edited by John C Sheehan Pp vii + 120 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd) Each 32s net

AMONG the 32 compounds for which preparative methods are described in Vol 37 are benzofurazan oxide, *trans*-2-dodecenoic acid, glutaric acid and glutarimide, norbornylene, parabanic acid, and *ar*-tetrahydro- α -naphthol, and the 31 preparations of Vol 38 include diphenylacetaldehyde, hendecanedioic acid and several related compounds, monobenzal and monobromo-pentaerythritol, monovinylacetylene, *trans*-stilbene oxide, and 2-vinylthiophene. Each volume has a cumulative index extending back to Vol 30. Four enclosed leaflets direct attention to explosions that have been experienced in preparing ethyl azodicarboxylate, methoxyacetylene, and *o*-toluamide, and in storing *p*-tolylsulphonylmethyl-nitrosamide.

JOHN READ

Trends in Birth Rates in the United States since 1870

By Bernard Okun (The Johns Hopkins University Studies in Historical and Political Science, Series 76, No 1) Pp 203 (Baltimore, Md The Johns Hopkins Press, London Oxford University Press, 1958) 3 50 dollars, 28s

THIS monograph consists of three essays. The first two discuss the secular trend of the declining birth-rate in the White and Negro population of the United States, respectively. The method used is an analysis of fertility indices (the ratio of children to the total population, and the ratio of children to women of reproductive age) in different States of the U S A. The discussion will be of interest mainly to the specialist in demography, and adds little to what is already available in the monograph by Grabill, Kiser and Whelpton, who have surveyed the material in much greater detail. The third essay, however, is of more general interest. Here Dr Okun surveys the hypotheses and approaches used in explaining birth-rate trends, and attempts a classification and an assessment of the methods that can be used to test the hypotheses. No very definite conclusions emerge, but the essay is a useful summary.

The Structure of Glass

Proceedings of a Conference held at Leningrad, November 23-27, 1953 Translated from the Russian by E B Uvarov Pp ii+295. (New York Consultants Bureau, Inc, 1958) 20 dollars

THIS translation was sponsored by the Glass Division of the American Ceramic Society and the National Science Foundation with the expressed object of providing a general look at the status of glass science in the U S S R, and admirably does it fulfil its purpose. The fact that this conference was attended by more than 500 delegates from twenty-eight towns of the Soviet Union is itself impressive, and conveys immediately an idea of the large scale on which research in this field is being conducted.

As a report of a conference the volume is excellent, the printed discussion is particularly lively, and occupies 70 pages, 42 papers were communicated to the conference and these account for 228 pages of the volume. Remembering that the conference took place five years ago it would appear that at that time there was no great difference between the topics being discussed in the U S S R and in Western circles.

It would be easy to dismiss the discussion as being concerned too much with semantics and to criticize some of the ideas put forward. However, examples of similar ideas and arguments are well sprinkled through the literature. The great argument of the conference was on the rival merits of the 'random network' theory of glass structure and the 'crystallite' theory. The proponents of the crystallite theory attacked their opponents on the ground that the randomness was not complete, while their own definition of 'crystallite' was hedged by sufficient qualifications to make it clear that the majority of them did not mean that term to imply anything that could properly be described as a crystal.

Perhaps the fairest summing-up is that here there is realization that the network theory of glass is only a first approximation—a view which is receiving increasing emphasis at the present time.

The translation was well worth while, and all interested in the physics and chemistry of glasses will enjoy reading the book.

R W DOUGLAS

LIBERTY IN AN AGE OF SCIENCE*

By SIR SOLLY ZUCKERMAN, C.B., F.R.S.

Department of Anatomy University of Birmingham Medical School Birmingham

IF, two or three decades ago, one had spoken of science and liberty in the same breath, the emphasis would have been different from my present theme. That period was the era in which the social function of science was a central issue of debate and it culminated in the almost total mobilization of the scientific forces of our two countries during the Second World War. This War was the turning point. Where previously scientists were seen according to the interests of the observer either as dedicated scholars, or as the source of invention or as the technical guardians of the social services on which an urban civilization depends to-day they also appear in a number of new guises—as the backbone of national defence, as pioneers of outer space, and even as the counsellors of presidents and prime ministers.

The world has come not only to recognize but also to insist that science has a social function, but, not all the world. There have always been those who have questioned whether the democratic way of life, and a life of liberty can survive the stresses of rapid economic growth, and as the hazards of our century mount, their numbers are being reinforced by others who are fearful lest all society becomes a victim of the forces that have been unleashed in our present scientific age. "The scientists think they are God" one exclaims "they want to remake the universe and we pay the price for their mad ambition."

This is no lonely voice, and it is one that has been heard before. Long before the days of artificial Earth satellites, long before the era of nuclear weapons. George Gissing wrote "I hate and fear science because of my conviction that for a long time to come if not for ever it will be the remorseless enemy of mankind. I see it bringing a time of vast conflicts, which will pale into insignificance the thousand wars of old and as likely as not, will overwhelm all the laborious advances of mankind in blood-drenched chaos."

But what science is thus that is the enemy of mankind? Surely not the pure thought or theory which enhances man's understanding? It is well to consider out of what confusion it is that science presents this ominous look.

The cultivation of science, by which we mean the quest for new natural knowledge through controlled and reproducible observation, can be treated as an endeavour which is either personal and private, or social and public. But however pure or personal may be the object of acquiring a scientific understanding of the universe in which we have our being, science inevitably becomes social or public not only because there can be no awareness of the existence of a new scientific idea until it is communicated from one person to another, but also because pure science frequently turns out to be basic to some practical development—to some piece of applied science—or to some convention of thought which then starts

transforming the environment within which it was distilled. So it is that pure science and applied science have progressed hand in hand over the years, the pure fertilizing the applied with ideas and the applied often providing the pure with the physical apparatus to help in the next intellectual leap forward.

This process has been a major factor in the progressive replacement of superstition by rational theory. And as Condorcet—that great French scientist of the latter half of the eighteenth century who was so powerful a protagonist of human dignity and freedom—wrote "The progress of the sciences ennobles the progress of the art of education which in turn advances that of the sciences"—a reciprocal operation which he did not exaggerate by describing "as one of the most powerful and active causes working for the perfection of mankind."

Man's evolution has also meant the continuous transformation of his social institutions through the directed application of pure scientific knowledge. We talk to-day of living in a new age of science of a world in the throes of a new scientific revolution but there is nothing new about this revolution except its speed and its greater hazards. Science has always revolutionized society ever since some basic discoveries in animal husbandry and crop cultivation made it possible for nomadic life to give way—to ten to twenty thousand years ago—to permanent village settlements, and so to the diversification of labour and the beginning of trade.

The transformation of society by scientific discovery and application has continued ever since, sometimes so slowly that decades pass before the historical record reveals much change, sometimes as at present with ever mounting force. While it could be argued that the technical advances of the past ten to twenty years transcend those of the rest of human history, that the speed with which new discoveries are disseminated and applied is now unprecedented, that the political and economic consequences of all this scientific activity will prove far more profound than those which resulted from past epochs of discovery, there is nevertheless no immediate reason to suppose that the social process which is involved in to-day's scientific revolution is different in kind from what was entailed in previous phases of rapid change.

If we are to understand the confused position in which the layman and the scientist now stand in relation to each other, we need therefore to examine certain features which characterize the growth of scientific knowledge, and also some which relate to its present impact on social affairs.

What, first do we mean by the need for scientific freedom as it applies to the pure scientist? One means not only the freedom to investigate those problems which one seeks ~~oneself~~, the fact that significant advances in ~~not be ordered by dogma~~, requires its special

* Substance of the address delivered at the Sixty-fifth Commencement Exercises of the California Institute of Technology on June 12.

thermodynamics, of relativity, or of natural selection, undoubtedly had their antecedent relations, no one could have predicted, before it actually occurred, if, and how, and when any of these major advances in our scientific understanding was to have taken place. Nor would it be possible to force a scientist to make this or that specified discovery. For example, genius though he was, no one could have prevailed upon Charles Darwin, say, in 1830 when he was twenty years old, to anticipate the basic genetic law revealed by Gregor Mendel thirty-five years later. One can employ special measures to encourage this or that branch of science. One can provide the conditions in which pure science flourishes, by multiplying the opportunities which make it possible—the universities, the laboratories, the freedom from other responsibilities. But having done these things, one can only then wait to see what emerges. One cannot in advance specify the shape and content, or determine the possible impact of what is not yet known.

Being unpredictable, it follows that the untrammelled emergence of new scientific ideas is not compatible with any restraint on the liberty of the scientist to roam where his fancy leads. Indeed, once the growth of any set of scientific ideas becomes constrained, it stands in danger of becoming obstructive dogma. A valid scientific hypothesis is never more than the best statement which, for the moment, can be made of the relations of the matters to which it refers, and should be swept away as soon as a better one emerges.

The growth of science thus necessitates freedom, even the freedom to be revolutionary. How then is stability to be achieved in a world in which science has so great an impact? How does science become, as it has often been described, the servant and the handmaiden of freedom?

One's immediate answer is that since economic and military power are to-day proportional to the degree with which scientific knowledge is exploited, science is the defender of the ideal of freedom on which Western democracy rests. In a more particular sense, as many have pointed out before, the applications of science have also provided the apparatus which has made central government powerful.

But surely science is in these respects no more the servant of the democracies than of the authoritarian regimes poised against them, and of the philosophical and political concepts on which they, in turn, are based. In a world of conflicting power, science is both the arsenal and instrument of power—but science *qua* science is always a neutral arsenal and a neutral instrument.

We cannot invest pure scientific knowledge with any inherent moral direction. That is imparted by the way science is used, and we can be certain, therefore, that all sides in the present world struggle will use science and technology in the achievement of their respective national aims, and also in whatever efforts they may make to narrow the over-widening gap between the developed and under-developed territories of the world.

My first main point, therefore, is that while the growth of fundamental scientific knowledge necessitates complete freedom from restraint, science is not uniquely associated with the preservation of freedom either in the personal or social sphere.

But there is a deeper issue underlying the relation of science and freedom. Let me first define the sense that I propose attaching to the concept of freedom

on liberty, which both in isolation, and as the ideal which annunates democracy, has always been a major concern of philosophical discussion.

By freedom I mean here the liberty an individual enjoys after the infinite number of degrees of freedom which are open to him in the abstract have been reduced by, say, the give-and-take of social life, still leaving a vast area of choice within which he could either engage in, or desist from, any particular activity. It was essentially in this sense that the great utilitarians of the industrial revolution—Bentham, John Stuart Mill and others who joined them in the battle for justice—conceived of freedom in the ideal society—a society which is governed by common consent for the common good, in which the greatest number enjoy the greatest happiness, in which there is equality of suffrage, and in theory, at least, in educational and economic opportunity, and in which laws and institutions, regulating the behaviour of individuals, are there because the unlimited exercise of one man's liberty would inevitably impose restrictions on that of his fellows.

It is essentially in this social sense, however 'negative' it may be, that liberty is implied in the proposition that science is its handmaiden. Science may, of course, well be the handmaiden of equality in the economic sphere, given, of course, the right political institutions. But is the proposition true in the philosophical sense of the term 'liberty', whether in relation to the concept to which I am directing my observations or to any other idea of liberty which philosophers have examined? Can it be true of the actual environment within which we exercise our freedom—an environment which is not some unreal stratosphere peopled either by abstract shadows of human beings or of social groups? Surely our social environment is a real one which is constantly being transformed by new scientific ideas, and by the application and practical development of these ideas. This transformation constitutes more than a process whereby men are conditioned in their thoughts and actions. Whenever some major development is pursued, for example, the development of machines based on steam, it means that some other path that potentially might have been followed was not followed. A material civilization of motor cars, of radio, of synthetic fibres, of nuclear power is not necessarily the only form a material civilization might have taken. But now that it has taken that shape, it helps define for us the content and boundaries of the area within which we exercise our freedom.

Liberty, in the sense I am using the term (and I believe to most political philosophers), means the power to act freely within the compass of the institutions which a people may set up in the exercise of their sovereign power, which implies their right to act as they think best as a collective body and which, according to legal theory, "is not restrained in any way except by the limitations inherent in human nature". It is irrelevant here that the exercise of democracy may not infrequently depart from its ideals, or that the institutions which had to be set up to preserve the hard-won freedom of modern times may themselves have eroded the principles they were meant to preserve. The point I wish to make is that science, through its practical impact, is to an increasing extent, almost to a dominant extent, determining the way the presumed uninhibited sovereign power expresses itself. Because of its achievements in eliminating disease and alleviating pain, through

the food and wealth it has brought, most people to-day prefer to regulate their lives in accordance with scientific discovery rather than in any other way. In that sense they are prepared to constrain their abstract liberties in accordance with what science unfolds and the riches it brings. Is the choice, we may ask, conscious? Can we know for what it is we are opting? Hobbes, like other philosophers, found liberty consistent with necessity. Is liberty truly consistent with necessity, when necessity is determined by science? Is the sovereign power consciously deciding to develop thus or that scientific discovery, and so to determine social development in this or that direction? Or is it merely adapting itself as best it can to what comes out of Pandora's scientific box?

The answer to any of these questions is inevitably bound up both with the constraints and unpredictability of any new major scientific advance. Of course, there are always certain fields of science which are more popular and better supported than others. Scientific knowledge never develops evenly over the whole potential field of knowledge. But in so far as scientific activity is in general confined by past discovery to certain areas, so is our abstract liberty, in effect, constrained. Furthermore in any field of science several alternative courses of action might be pursued in search for a solution to a problem. In choosing any one of them the research worker may deny himself, and others the opportunity of pursuing another. There is also the increasing complexity of the scientific knowledge which is now being transformed into new remedies, new chemicals, weapons systems, and so on. The facts which these days transform our lives become more and more difficult to comprehend and on occasion are still not fully decided when they are applied. If this were not so would there still be debate—I choose the most urgent example of all—about the hazards associated with radioactive fall-out?

Above all is the fact that the nature and magnitude of potential discovery cannot be defined in advance any more than can its impact on our social lives. As de Toqueville wrote: 'We entrust ourselves to the future, an enlightened and impartial judge—but one who sits, alas, always too late.'

Faraday, Hertz, Curie—what could they have known of the ultimate uses to which their discoveries would be put in the field of electric power, radio and nuclear energy, or of the social and political consequences of their uses? We ourselves, years later, cannot tell what these consequences will be. Can we to refer to just one more vital question out of many now once this scientific age is generating, commit ourselves now to more than arbitrary views of the possible political consequences of the elimination of disease and of its complementary change, the explosive growth of population in so many areas of the globe?

Science has created wealth, it has helped in the struggle for freedom from economic exploitation, it has redistributed power. But in doing these things as it widens the area of material choice, it circumscribes and determines the environment in which we exercise our abstract liberties. That is my second point. Itself demanding freedom and revolutionary in its ways, science is now determining in an increasingly unpredictable way, the main issues about which we as citizens, exercise our freedom of choice. Can there be much more than a fictional verity to the abstract idea that an area exists within which

man can enjoy the capacity of unconditioned or untrammelled choice?

Democracy was man's answer to tyranny and exploitation. The only form of exploitation it will never help overcome is the coercion of new knowledge, which by guiding our social lives into certain channels, limits advance in other directions, the new knowledge which focuses the interests of humanity on goals which cannot be properly charted until they have been achieved. To the philosopher, as I have said, ultimate limitations on the freedom of the individual are set by the inexorable laws of Nature. To the scientist, the limitations are set by the particular laws of Nature man himself discovers, out of a potential infinity of such laws and from the use to which he puts these laws.

Up to now we have been able to claim that the applications of science have increased the sum total of human happiness. But to-day we stand at a cross road. The process of applying scientific knowledge is as endless as is the prospect of gathering new knowledge, and the basic scientist is responsible for only the beginning of the cycle of activity which creates a demand for the application of his discoveries. Industrialization has established itself as the one cure for poverty in a world the bulk of the population of which still lives by subsistence farming and history as yet gives no example of any but small communities which have voluntarily turned their backs on higher material standards of living. Instead a uniformity of desire and demand is generated for the so-called good things of life as the one world discovers how the other lives and what it itself lacks. Obviously we cannot say that the economic history of the West will be recapitulated as industrialization spreads and as the chains of the past are broken in distant parts of the world. But we can be all but certain that neither the needy nor the rich will allow the process of applying the fruits of scientific knowledge to stop, either in the national or the international frame. In this process means become ends, because as new ways of doing things are discovered they transform the things being done and so their purpose. In these days it is only in theory that one chooses weapons and tactics to achieve a strategy. In fact weapons often end by determining strategy—and sometimes the purpose behind the strategy.

In my view it is against this force of scientific application that the Gensings of to-day rail—not against science as such and it is this force which could construe our democratic liberties and which, if we ceased being vigilant, could even constrain the liberty of pure and basic science—and by so doing paradoxically destroy itself.

Ideally we think that democracy to-day means government by the representatives of the people by consent of the people. But many to-day also feel that the sovereign power, the people, has through a process of negative democracy, abdicated its rights to a power elite, to a bureaucracy to what you will which is consciously determining the directions we follow. This it seems to me, is again too simple. The element of the unknown in government increases with every step we are now taking to apply the fruits of science. If sovereign power is being abdicated it is less to some governing body, however formed, and more and more to a process of applying scientific knowledge without any real possibility of determining its final consequences. Neither the voice of the majority, nor those through which it is expressed, can proclaim the precise lines of the future.

Where do scientists stand, as ordinary citizens, in this process whereby the application of the fruits of their discoveries can become a potential prison for our abstract liberties? It is argued that because of their special knowledge scientists can be aware of the danger and promise arising from their discoveries, and that therefore they have a special responsibility in relation to the most pressing problems of our time. I should agree with this, if it meant no more than that scientists are better able to appreciate the scientific facts. For how can the scientist as such, who is not responsible for its application, accept the responsibility for predicting some vast social transformation that might result from what seems an innocent observation at the time it is made?

But I should agree all the more if one coupled with this view of the scientist's responsibility the thought that in the problem of preserving our liberties lies the most important reason for regarding an education in science as constituting to-day an essential part of an education in the humanities. For if an understanding of social and political purpose is one of the aims of the liberal arts, then that aim cannot be realized until their scope is widened to embrace a proper understanding of the scientific knowledge the application of which is now so rapidly transforming our intellectual and material environment.

Science, technology and humanism seem to have assumed that order of importance in the determination of our affairs. I do not know how it is in the United States, but over the post-war years the changes which the tacit application of science and technology have occasioned in Great Britain seem far more profound than any that have been brought about through the overt discussion of social values or social goals. If this kind of thing is happening, can the humanities continue as a potent educational discipline without encompassing an understanding of the social forces which derive from the application of the natural sciences? Scientific literacy, we are told in a recently issued report on education, will need to be far more widespread than it is "if we are to solve the problems of this age". Undoubtedly this is needed, but alone it is not a sufficient condition to ensure the solution of our problems—for here I agree with Aldous Huxley that "higher education is not necessarily a guarantee of higher virtue or higher political wisdom". What we most need to learn is that in the major scientific matters which now affect human destiny, one cannot safely take decisions for to-day unless we realize that those same decisions determine the future. This realization may not lead to the right decisions, but it might help obviate some of the worse.

SATELLITE OBSERVATIONS OF SOLAR COSMIC RAYS

By PAMELA ROTHWELL and CARL McILWAIN

State University of Iowa, Iowa City

ON three occasions during August 1958, large increases in the intensity of charged particles outside the Van Allen radiation zones were detected by the *Explorer IV* satellite 1958 epsilon, at high magnetic latitudes and rather low satellite altitudes (270–650 km), where the Geiger tubes carried in the satellite normally count only cosmic rays. Figs 1, 2 and 3 show that the charged particle intensity in both counters increased sharply with magnetic latitude, above about 60°, on August 16–17, August 23–24 and August 26–27. (We have defined 'magnetic latitude', λ_{dip} from the magnetic dip angle δ at the point of observation, through the dipole relation $2 \tan \lambda_{\text{dip}} = \tan \delta$.) Different symbols have been used for each satellite pass on any one day, recorded at the microlock station in Van Buren, Maine, in the geographical longitude range (95° W–45° W). The

time-interval for each pass (usually about 5 min duration) is given, and each point has been characterized by the altitude in kilometres at which the observation was made. The charged particle detectors in the satellite have been described in detail elsewhere by Van Allen *et al.*¹ The two Geiger counters (one shielded with 1.6 gm/cm² lead, and the other unshielded except by the satellite hull) could detect protons of energies greater than 40 MeV and 30 MeV, respectively, and electrons of energies greater than about 5 MeV and 3 MeV. The omnidirectional geometric factors ranged from 0.140 cm² to 0.823 cm² in the shielded counter, and from 0.140 cm² to 0.705 cm² in the unshielded counter. Table 1 gives the upper and lower limits to the omnidirectional fluxes of particles which would produce the highest observed counting rates in (a) the unshielded counter

Table 1

| Date August 1958 | Time of satellite pass (UT) | (a) Flux through unshielded Geiger counter (particles/cm ² /sec) | (b) Flux through shielded counter (particles/cm ² /sec) | (c) Ratio of counting rates unshielded/ shielded | (d) <i>E</i> _{min} (MeV) | (e) <i>E</i> _{max} (MeV) | (f) Elapsed time after 3 + solar flares (hr) |
|---------------------|-----------------------------------|---|---|--|---|---|--|

Fig 3

(J_{eq}), (b) the shielded counter (J_{sh}), and (c) the ratio of these counting rates (unshielded/shielded) at each satellite pass on which an increase in intensity was observed. The cut off energies for protons, at (d) the highest magnetic latitude on each pass (E_{min}) and (e) the lowest latitude at which counting rates in excess of the cosmic ray rate were recorded (E_{max}), are estimated from the local values of the Earth's magnetic field.

The particle fluxes are at least one or two orders of magnitude greater than the normal cosmic ray flux. It seems unlikely that these intensity increases are due to soft particles from the outer Van Allen radiation zone, because

(a) *Explorer IV* cuts through the outer zone (as observed with the Geiger counters) at about 56° magnetic latitude, that is, farther south than the intensity increases reported here.

(b) The ratio of counting rates between the unshielded and shielded Geiger counters in the outer zone is typically, about 30 or 40 to one, in contrast to the comparable counting rates observed in both counters at the higher latitudes.

The ratios unshielded/shielded are reasonably consistent with the hypothesis that the charged particles are protons the energies of which lie between E_{min} and E_{max} . The wide limits placed on the estimated fluxes are due to the uncertainty in the absolute geometric factor for the counters in the proton energy range 30-100 MeV.

We suggest that the intensity increases are in fact due to solar protons, associated with the large solar flares which occurred at 0432 UT on August 16, 1417 UT on August 22 and 0005 UT on August 26. Strong support for this suggestion is provided by measurements made from balloons and with rocket motors during this period.

(1) Anderson⁴ and Winckler *et al*⁵ measured an increase in charged particle intensity at balloon altitudes above Churchill, Canada (magnetic latitude 77°), and Fairbanks, Alaska (magnetic latitude 64°), on August 22 and 23, and have identified the particles as solar protons of energies up to a few hundred MeV. It is almost certain that the satellite has recorded the same event. (The increased intensity was not observed until August 23 because there was no pass over Van Buren after 1100 UT on August 22.) Anderson *et al*⁵ deduce a differential number energy spectrum $n(E)dE = K(t)E^{-(5 \pm 0.2)}dE$ (where t is the elapsed time after the solar flare) for the solar protons in the energy-range 100–400 MeV. At 1115 UT on August 23 they estimate that the flux of particles with energies greater than 100 MeV was about $1.5/\text{cm}^2/\text{sec}$. Intensities observed from the satellite at that time suggest that a spectrum of this form may well extend down to about 30 MeV.

(2) Leinbach and Reid⁷ have suggested recently that the absorption of cosmic radio noise, measured with riometers following large solar flares, is due to ionization of the upper atmosphere by solar protons. H. Leinbach (private communication) and Hultquist and Ortners⁸ have observed three such events, commencing August 16, August 22 and August 26, in the riometers at Thule (Greenland), Fairbanks (Alaska) and Kiruna (Sweden). Absorption effects of this type occurred on twelve other occasions, between July 1, 1957, and September 30, 1958 (H. Leinbach, private communication).

During the period August 16–27 no increase in intensity was observed in the Canadian cosmic-ray neutron monitors at Resolute, Churchill, Sulphur Mountain and Deep River⁹ at magnetic latitudes of 88°, 77°, 61° and 62°, respectively, but it is not surprising that protons with a steep number-energy spectrum and maximum energies of a few hundred MeV produced no detectable effects near sea-level.

The ratio of the maximum counting rates in the two counters increased significantly during each event. This suggests that either (a) the shape of the energy spectrum of the solar protons changes, and relatively more low-energy particles arrive at later times, or (b) that some particles with energies below the usual magnetic cut-off energy can arrive at a given location later in the event.

Freier *et al*¹⁰ have, in fact, reported that protons with energies below the usual measured cut-off were found at balloon altitudes over Minnesota on March 26, 1958, three days after a large solar flare, and at the time of a magnetic storm. When the Earth's field is disturbed, some charged particles can probably be admitted to regions normally 'forbidden' to them, and particles with energies below the normal cut-off may arrive at a given latitude during, and perhaps for some time after, the disturbance. During the period August 16–27 'sudden commencements' occurred at 0622 August 17, 0228 August 22, 0140 August 24, and 0303 August 27.¹¹ The lowest ratios unshielded/shielded occurred on August 16 before this period of magnetic activity.

There is now evidence from several sources which strongly suggests that solar protons with energies up to a few hundred MeV quite frequently bombard the upper atmosphere at high latitudes for some days following a large solar flare. The five widely observed, extraordinary increases in cosmic-ray intensity near sea-level which have occurred during the past twenty years of continuous observation are probably unusually energetic examples of a common solar phenomenon, namely, the acceleration and ejection of protons with energies approaching those of galactic cosmic-ray particles.

We should like to thank Prof. J. A. Van Allen and Dr. K. A. Anderson for many interesting discussions. This work has been assisted by the U.S. International Geophysical Year project 321 of the National Academy of Sciences, the U.S. Army Ordnance Department, the Office of Naval Research, and the Atomic Energy Commission.

A BORE-HOLE TO THE EARTH'S MANTLE: AMSOC'S MOHOLE

By GORDON LILL and WILLARD BASCOM

AMSOC Committee, National Academy of Sciences—National Research Council, Washington, D.C.

MAN'S knowledge of the interior of the Earth has been largely obtained by indirect methods, and although a great deal is now known about the qualities that subterranean materials must possess, numerous uncertainties remain. There is now a project under way, sponsored by the AMSOC Committee of the U.S. National Academy of Sciences to obtain corroborative evidence about the nature of the interior of the Earth by the direct method of drilling a hole completely through the oceanic crust to obtain samples of the mantle. Since the boundary between the crust and mantle is known as the 'Moho'

(after Prof. A. Mohorovičić of Yugoslavia, who first described the seismic discontinuity there) it seemed reasonable to contract the project name to 'Mohole'.

The American Miscellaneous Society, founded in 1952 as a whimsical reproof of scientific societies which are sometimes too specific for their own good, uses its cable address, AMSOC, in the alphabetical world of Washington. It has no formal members, officers, by-laws or publications, and there is a bent towards geophysics.

On the subject of drilling through the crust of the Earth, however, the AMSOC group has been formally

organized so that it can receive funds from the US National Science Foundation. The original members of the Committee were Gordon Lill (chairman), Prof Maurice Ewing, Dr William Heroy, Prof Harry Hess, Dr Harry Ladd, Dr Arthur Maxwell, Prof Walter Munk, Prof Roger Revelle, Dr William Rubey, Dr Joshua Tracy and Willard Bascom (technical director).

The Mohole project in more or less its present form was born at a breakfast at Prof Munk's house in California, at which he led the conversation on the need for a geophysical analogue for the space exploration programme. The suggestion of Dr Frank Eastabrook, made in *Science* (October 1956) for the digging of a "Geophysical research shaft", had set forth the principal scientific advantages of direct sampling. But AMSOC, unaware at the time of that suggestion, proposed a deep drilling project.

The following September in Toronto, at the meeting of the International Union of Geodesy and Geophysics, a resolution was passed "urging the nations of the world to study the feasibility and cost of an attempt to drill to the Mohorovičić discontinuity at a place where it approaches the surface". A hole 10-15 km deep on an oceanic island was suggested. The sponsors were Harry Hess, Roger Revelle and T F Gaskell.

The question of the structure and material of the interior of the Earth is a puzzle which has long challenged the mind of man. In all major aspects the most acceptable present hypothesis holds together very well. This is remarkable, for it requires that there be reasonable agreement between at least eight sub-sciences, all of which make indirect measurements. Studies of astronomy, meteorites, volcanoes, geological structure, gravity, seismic waves, the magnetic field, and heat flow each contribute to the total knowledge.

If one assumes that meteorites are the wreckage of a planet similar to the Earth and that the rocks spewed out by volcanoes (the volcanic precursors of which begin well below the Mohorovičić discontinuity) contain samples of mantle material, then we already have samples of the deep rocks. Moreover, Harry Hess believes that mantle rock actually outcrops (at St Paul's Rocks in the mid Atlantic, in Japan and in California). Astronomical observations give the total mass, the average density and the moment of inertia of the Earth.

But in the main, evidence about the interior of the Earth has come from earthquake waves. By the combination of tedious computation and great skill, seismologists have worked out characteristics of the planet which keep within the limits set by the other evidence.

Fig 1 The Interior of the Earth

The hypothesis of inner and outer cores surrounded by a thick mantle and capped with a thin crust has stood the tests of many years. Now the problem is to refine the information and to obtain evidence which cannot come from further advances in seismology. The composition of the mantle, which represents about 85 per cent of the volume of the Earth, is the principal problem of geophysics to-day, for although a lot is known about it, uncertainties remain (Fig 1).

The exact mineralogical and rock composition, the density, strength, temperature, the amount of radio activity, the thermal and electrical conductivity—all these will contribute immeasurably to the understanding of the Earth and its origin. Moreover they will serve to enhance the value of the indirect geophysical measurements. Finally some new and entirely unexpected piece of evidence may be unearthed that will cause science to revise substantially its concept of the Earth.

The crust is closer and easier to study than the interior, but even so it is more controversial. Generally it is agreed that continents represent relatively thick blocks of andesitic rocks, and that ocean basins are composed of much thinner basaltic rocks—the average thicknesses being about 30 km.

AMSOC believes that this series of holes which will eventually sample the mantle of the Earth is likely to produce the greatest advances in man's knowledge of the Earth in our time

ASYMMETRICAL DELIVERY IN RABBITS

By DR. LUIZ MACEDO COSTA* and DR. ARPAD CSAPO

The Rockefeller Institute, New York, 21

THE experiments of Corner and Allen¹ and Allen and Reynolds², performed on rabbits, premised an understanding of the mechanism by which pregnancy is maintained and terminated in mammals. They also provided us with a key substance which controls these processes, the ovarian steroid progesterone.

The thirty years which followed these discoveries, however, brought disappointments. The different consequences in different species of ovariectomy or oxytocin infusion upon pregnancy, the lack of correlation between uterine activity and the concentration of progestational compounds in body fluids, and the lack of success in predicting effective progesterone therapy in women led many investigators to believe that either progestational compounds do not have a key role in the control of the pregnant uterus, or else a variety of mechanisms operate in different species.

These conclusions are challenged by a striking experiment of Nature which strongly implies that the maintenance of pregnancy is more a local than a systemic affair, thus allowing an explanation of the

differences cited above. When a woman who has a duplex or bicornate uterus bears twins, one in each horn, the infants may be born several weeks apart, showing that in the same woman at the same instant conditions can be appropriate for the maintenance, as well as for the termination, of pregnancy³.

Classical endocrinology limits our thinking to a systemic hormonal control of the uterus by which the glandular product is distributed uniformly in the target organs. This simple experiment of Nature, however, suggests to us that such a systemic control may not operate in all instances. A 'local' effect may be considered instead, when the organ of secretion and its target are in direct contact, allowing diffusion of an active compound from one cell to the next. Thus the local effect of placental progesterone has been postulated and described⁴ as an alternate mechanism.

The existence of such a local mechanism could explain present controversial issues concerning the mechanism of the maintenance of pregnancy. Species differences could be looked upon not as differences in basic principles, but, for example, as differences in timing and in magnitude of the shift from ovarian (systemic) to placental (local) progesterone effect, or

Fig 1 Schematic illustration of the type of operations used in the present study (upper row). Crosses over the ovaries represent ovariectomy, crosses over the conceptuses, placental dislocation. Arrows indicate intraamniotic injection of 2 mgm progesterone in 0.04 ml oil. The lower row represents the effect on delivery of the operation or treatment.

[Fig. 2. Asymmetrical delivery in rabbits induced on the twenty-fifth day of pregnancy. The numbers on the left represent the type of operation as illustrated schematically in Fig. 1. The first picture on the left is taken immediately after the operation, the second is made on repeated laparotomy after delivery is completed in one horn and the third after the undelivered horn is opened and the fetuses and placentas examined.]

as differences in the metabolism and elimination of progesterone, dependent on the exposure of progestational compounds to the systemic circulation, prior to their uptake by target organs. The concentration of progestational compounds and their changes in concentration in body fluids would not be expected to reflect quantitatively the endocrine condition of the uterus because much higher concentrations than occur in the blood or in the urine could be present in key positions at the myometrial cell, in fact, body fluids may contain only the 'leakage' of a local arrangement or what is left from destructive and eliminating processes. The lack of conclusive evidence for the effective use of progesterone in therapy would become a challenge than this appointment because an effect

placental progesterone could be therapeutically initiated only by a similar local application, or by forms of progesterone not subject to systemic destruction.

To demonstrate a local effect of placental progesterone on the myometrium, we studied thirty-five pregnant rabbits in the present experiments. It is generally believed that pregnancy in rabbits is entirely maintained by ovarian progesterone not supported by placental contribution. We suspected, however, that even in rabbits there may be progesterone production or effective metabolism, in the placenta in late pregnancy^{4,5,6}. In women on the other hand, during the last six months of pregnancy the placenta seems to substitute completely for the endocrine function of the ovaries⁷.

In our colony of New Zealand white rabbits labour can be induced with 1 i.v. Pitocin (Parke Davis), intramuscularly, in 94 per cent of the animals 31 days after mating. Only 7 per cent of the animals deliver after similar treatment (even if repeatedly applied) if the animal is less than 30 days pregnant.

We ovariectomized rabbits bilaterally (op No 1) on the twenty-fifth day of gestation (duration of pregnancy = 32 days) and found that 13 hr after the operation 1 i.v. of 'Pitocin' successfully induced delivery.

If the ovaries were not removed (op No 2), but all the placentas in both uterine horns were dislocated (by gently pressing the uterine horn at the placental implantation site) placental function ceased and delivery was successfully induced by 'Pitocin' 20 hr later. Thus is evidence that the rabbit placenta is indispensable for the maintenance of pregnancy.

If the two procedures ovariectomy and placental dislocation, are combined (op No 3) labour can be induced 9 hr later. These observations suggest that in the rabbit both the ovaries and the placentas contribute to the maintenance of pregnancy. When both these possible sources of progestational compounds are removed the myometrium has enough stored material to defend pregnancy for 9 hr against the labour inducing effect of 1 i.v. 'Pitocin'. The placentas can prolong this period for four additional hours and the ovaries for 11 hr. This suggests that the ovarian contribution is three times as great as the placental.

If after any of these operations 'Pitocin' is not administered, spontaneous delivery ultimately occurs but the time between operation and delivery, as well as the time needed for delivery, is greatly prolonged. Also, the mother may destroy or partly eat the

uterine contents, which makes accurate timing and observations difficult. For this reason we induced labour with 'Pitocin'.

It may be argued that the rabbit placenta only stores, but does not produce, an active progestational compound. The following experiment, however, suggests that the placental contribution is not only storage, but also synthesis or effective metabolism. If ovariectomy is combined with the dislocation of one set of placentas, in one horn only (op No 4), this horn alone delivers 9 hr later on 'Pitocin' administration, whereas pregnancy is maintained in the other horn. Thus asymmetrical delivery, resulting from the presence of a set of functional and another set of non-functional placentas in two horns, respectively, is indication of the production of an active compound as well as evidence of the local effect of the placenta.

It might be said, however, that the active compound of the placenta is not like progesterone, but is an entirely different compound. This is unlikely, since the local effect of the dislocated placentas can be substituted for by the injection of 1-2 mgm progesterone into the amniotic sac. If only one horn is treated with progesterone in the ovariectomized animal, delivery is always asymmetrical. The untreated horn delivers first, irrespective of whether the placentas in one horn are dislocated or not (op Nos 5-8). The time when delivery occurs reflects a functional or non-functional set of placentas, but the phenomenon is the same, that is, delivery is asymmetrical if the distribution of progesterone is asymmetrical. Whether the litter is alive or not does not alter the picture, nor does the mechanical

irritation of the uterine horn during the operation.

These observations are best explained as follows. Pregnancy in rabbits is maintained by a joint contribution of an active progestational compound by the ovaries (systemic) and placentas (local). The placental contribution is less than that of the ovaries, but both organs are needed to maintain an effective concentration of the active compound in the myometrial cell. When the defence is effective, labour cannot be induced by 'Pitocin', if it becomes ineffective, labour can be induced. When the systemic effect of the ovaries is suspended by ovariectomy the local effect of the placenta controls the uterus and if this local effect is asymmetrical, labour is asymmetrical.

In women, an early and complete shift from ovarian to placental hormone production could result in a dominant local progesterone effect early in pregnancy. This would lead to an 'endocrine asymmetry', resulting in asymmetrical function. Such an asymmetry is exaggerated in a bicornate uterus when endocrine function in one placenta fails earlier than in the other. Functional asymmetry of the human uterus offers attractive explanations of puzzling problems concerning normal and abnormal pregnancy and delivery.

WARREN SPRING LABORATORY, STEVENAGE

IN setting up Warren Spring Laboratory at Stevenage "to carry out process research and development over a wide field not limited to particular areas of technology", the Research Council for the Department of Scientific and Industrial Research expressed its conviction that, when necessary, the Department's research stations should change in function and objective to meet the needs of changing situations. The Council considered that the Fuel Research Station had largely fulfilled the aims in view when it was set up, and that current needs were satisfactorily catered for by researches going on elsewhere, it decided, therefore, to close down the Fuel Research Station, and to transfer the staff to a new Laboratory in Stevenage, with new programmes. To ensure that there should be no likelihood of an impression being gained that the Fuel Research Station was being continued at Stevenage, or that the title of the new Laboratory might appear to restrict the field of activity, it is named after a lane which used to run across the site.

Of the work carried out at the Fuel Research Station only two programmes have been transferred to the new Station, namely, research on the abatement of atmospheric pollution, and on the synthesis of oils and chemicals by the Fischer-Tropsch process.

There had been a number of substantial indications of need for research in the field of mineral processing, and it was decided that this should form one of the new projects to be undertaken, there had also been indications of need for work on a pilot scale in various fields which the Department had not been able to meet. With these pointers, it was decided to build a laboratory in a modern industrial style, to be as flexible as possible, to house in the first place a staff about the size of that of the Fuel Research Station, and with facilities for both laboratory research and pilot-scale work.

The main three-story laboratory building is 372 ft long and 37 ft 6 in wide (Fig 1). It is based on a 4-ft module, which is expressed elevationally by vertical posts supporting floors and roof, and by internal posts centrally along the length. The main spine corridor is set to one side of the central supports. The only solid internal walls are those of the corridor and the secondary staircases, all other partitioning is of light, demountable, prefabricated construction, which can be placed in any desired position between the outer walls and the inner corridor walls, subject only to the basic 4-ft module.

Gas, water, electricity, compressed air are available at every third module (12 ft) along a perimeter distribution system.

Fig 1 The Warren Spring Laboratory Department of Scientific and Industrial Research

The building is heated by panel type radiators; made-up dummy panels matching them are inserted between the radiators to give the appearance of a continuous radiator panel along each wall between the concrete columns at 12 ft centres. The radiators and the dummy panels conceal the services which run around the perimeter of the building. The dummy panels can be readily removed when service connections are required. Fume cupboards are ranged along the inner, corridor walls, each cupboard having its own extract duct which discharges at roof level.

The finishes are simple, self-coloured, fair faced brickwork being used throughout, except in laboratories with special functions. With the exception of laboratories which are adapted for wet processes, floor finishes are in linoleum.

A three-story administration block runs at right angles to the main laboratory building, it is similar in construction and design except that there is a lower ceiling height.

There are three pilot-scale buildings, each 90 ft long by 55 ft wide by 37 ft 6 in maximum height. In two of them, a 20 ft wide section is 20 ft high only. These buildings are linked to the main laboratory block by a corridor with small scale laboratory units on each side. The buildings have folding doors to the side bays to permit the introduction of heavy plant at any point. The structure is carried by precast concrete posts. Vertical cladding above a brick protective walling, consists of asbestos-cement sheeting and patent glazing, the roofs are of asbestos-cement decking overlaid with bituminous felt.

The workshops and engineering stores occupy a large steel framed building comprising six east light bays each 60 ft by 30 ft minimum headroom.

Steam is required night and day for process purposes, two fully automatic, oil fired, high efficiency boilers are used with a nominal pressure of 120 lb/sq in. One is rated at 10,000 lb and one at 5,000 lb of steam per hour. The front of the boiler house is fully glazed with a patent system permitting removal in sections when boiler tube replacements are necessary, so that it is possible to reduce the dimensions from front to rear. A high level water reservoir, in reinforced concrete, has been designed integrally with the boiler flue (see Fig 1).

Service mains run in open, splay sided trenches to avoid the expense of underground ducts or the unsightliness of overhead gables.

The total cost of the establishment including buildings services fixed, laboratory fittings library bookshelves, and all site works was approximately £620,000.

Research Programmes

Atmospheric pollution Purely by coincidence the closing of the Fuel Research Station occurred simultaneously with the introduction of the Clean Air Act, it was therefore particularly apposite to review the programme in starting at the new station. The work now being undertaken follows naturally from that begun at the Fuel Research Station and is designed to meet the requirements of the Ministry of Housing and Local Government.

The principles of smoke elimination that have proved successful in reducing smoke from hand fired boilers on land are being applied to marine boilers. The possibility of developing after burners to burn smoke in various situations is being investigated.

The properties of smokes from different sources are being examined with special reference to the constituents that might be injurious to health. The occurrence of oxides of nitrogen in the atmosphere under different conditions is being studied.

In the new investigations of air pollution there is a need for greater accuracy than has been possible in some of the measurements made in the past. As a matter of urgency a review is being made of the principal instruments at present in use. This work is being undertaken by the Scottish Branch of the Laboratory at Thorntonhall.

Micro-surveys are in progress to examine the concentration of various types of pollution at different types of site in a limited area. The results of such investigations will be important, for example in helping to determine the value of smoke-control areas, and in assisting those responsible for deciding the height of siting of large industrial chimneys.

Process development Synthesis of oils and chemicals from carbon monoxide and hydrogen is being studied as part of a project to develop, if possible, an econ-

omic process for producing oil from coal. The development of oils from coal is a two-stage process: the first stage involves the complete gasification of the coal to yield a mixture of carbon monoxide and hydrogen, and the second the catalytic conversion of the gas mixture into the desired end-products. The work at Warren Spring Laboratory is concerned only with the second of these stages. Economic considerations indicate that the most promising version of the Fischer-Tropsch process for use under British conditions is the slurry process, in which the gas mixture is passed through a suspension of powdered catalyst in molten wax at temperatures of 250–300° C., and at pressures between 5 and 30 atmospheres.

The objectives of the programme are (1) to develop an iron catalyst of longer life and higher activity than those at present available and one that will yield a high proportion of desired end-products, (2) to select operating conditions (gas composition, temperature, pressure) to combine a high reaction velocity with a given distribution of end-products, (3) to obtain data necessary to design a full-scale reaction vessel.

Synthesis gas is produced on the site at a rate of 4,500 std cu ft per hr in a standard, water-gas generator operated by the Engineering Services Division. There are arrangements for feeding carbon dioxide with the steam so as to vary the hydrogen-carbon monoxide ratio between 1.15 and 0.6. The gas is purified from hydrogen sulphide in Gastechnik towers and washed with caustic soda to control the carbon dioxide content. It is then compressed to 15 atmospheres pressure in the first two stages of a four-stage compressor, passed through the active carbon scrubbers to remove organic sulphur compounds, and then further compressed in the third and fourth stages to a pressure of 120 atmospheres.

The study of catalysis, which has been proceeding over a number of years at the Fuel Research Station, has brought to the team concerned considerable experience which should prove of value in some of the new programmes which it is hoped to undertake in the future.

Mineral processing research and development. Dr M. G. Fleming, of the Bessemer Laboratory of the Royal School of Mines, has been appointed consultant to this Division.

It seems probable that for some time a fair proportion of the effort of this Division will be engaged on sponsored work on particular ores, but it is hoped that basic investigations will include (1) a study of grinding in the presence of additives such as surface-active agents, (2) the kinetics of bubble attachments to mineral surfaces, as a contribution to the knowledge in the field of froth flotation, and (3) a study of the behaviour of mineral particles in a high-tension field, and the modification of this behaviour by various surface treatments.

The laboratories are equipped to handle most laboratory-scale mineral-dressing operations such as flotation, jigging, tabling, heavy-media separation, wet and dry magnetic separation, and high-voltage separation. In the hydrometallurgical field, facilities are available for atmospheric and pressure leaching, for fluidized-bed roasting, chlorine metallurgy, and solvent extraction. Pilot-plant facilities enable primary crushing operations to be carried out on a scale up to 2½ tons per hour, and flotation plant is available for treating up to 1,000 lb per hr. It is possible to carry out full-scale tests with radioactive tracers. The Division has a Mineralogical Section,

but relies on the Physical and Chemical Services Division for its analytical work.

Many of the problems on which work is likely to be necessary concern overseas deposits. Already a number of requests for investigations have been received from overseas territories, and an Overseas Mineral Processing Advisory Committee has been set up to advise on the selection and priorities of the programmes of interest to these territories.

Chemical engineering. It will be apparent that chemical engineering must play a large part in practically all the major activities of the Laboratory, and the decision of the Research Council to transfer "the work on Chemical Engineering . . . carried out at the National Chemical Laboratory to Warren Spring Laboratory" will readily be understood.

The Division has three functions: (1) to carry out research on physical operations which play an important part both in processes which are under development in the Laboratory, and those in more general use in industry; (2) to undertake research in the field of chemical engineering sponsored by industry or by Government departments; (3) as a result of these functions to accumulate basic information in chemical engineering for use by other sections of the Laboratory and industry.

Bearing in mind work that is already going on elsewhere in the Department on heat transfer and on fluid flow, it is proposed in the first instance to concentrate on the field of mass-transfer, and in particular to obtain results which will permit more accurate prediction of the performance of gas-liquid contacting equipment, and thus to facilitate the design of distillation columns, gas-absorption towers and reactors of the liquid-phase type, of which the Fischer-Tropsch slurry reactor is a particular example.

Four main lines of study are being followed, namely, bubble dynamics, gas-liquid mass transfer rates, fluid mixing, and specific problems in gas absorption with chemical reaction.

The National Engineering Laboratory of the Department has sponsored work at Queen Mary College, London, on the synthesis of organic compounds for use as drop-wise condensation promoters and has evaluated their effectiveness. The proposed work at the Warren Spring Laboratory is being planned in consultation with the National Engineering Laboratory and is intended as a study of the mode of action of these promoters in order to facilitate the development of compounds which will be effective for prolonged periods with a wide range of metal surfaces. It is proposed to study the mechanism of attachment of synthetic promoters to metal surfaces by methods of radiochemical labelling and to observe the subsequent history of these substances under conditions of use in heat exchangers.

Physical and Chemical Services Division. This provides a comprehensive central service in the fields of analysis, both by chemical and physical methods, instrument development, physical measurement, and photography. Special equipment includes gas chromatography, quartz and infra-red spectrometers, and equipment for X-ray diffraction and fluorescence spectrometry.

Engineering Services. This Division has a drawing office which undertakes design of pilot-scale plant for the Laboratory; it has an industrial staff of approximately 120, and well-equipped workshops.

Intelligence. In addition to the library and editorial services which are essential to any research estab-

ishment, the Intelligence Division is setting out to provide an information and project appraisal service. A start has been made, for example, in building up a centre of information in mineral processing, by assembling data from a wide variety of sources in such a way that they can be used in research and industry.

From what has been described it will be apparent that there is a wide choice of field before Warren Spring Laboratory, and that at the moment the main problem is that of selection and of allocation of priorities. In addition to the factors which govern the work of other laboratories of the Department of Scientific and Industrial Research, there is the task

of undertaking sponsored work to a greater extent and on a larger scale. Such work may be carried out for Government departments or for industry, and it may be on a fully confidential basis. The special facilities of the Laboratory will also be available for use, in certain circumstances, by teams from industry, which can work in collaboration with the research staff of the Laboratory.

The programme is regularly considered by a Steering Committee, appointed by the Research Council, the present members of which are Sir Harry Jeppeott (chairman), Sir Harry Melville, Dr R. Holroyd, Mr D. A. Oliver and Mr S. H. Clarke.

OBITUARIES

Mr T. L. Eckersley FRS

THE death of T. L. Eckersley on February 16 removed another of the rapidly dwindling band of pioneers in the field of radio research, among whom he was notable both for his theoretical and practical work. His interest in electromagnetic waves was aroused while he was still at school at Bedales, but it was during the First World War, after studying at University College, London, and Trinity College, Cambridge, with some years at the National Physical Laboratory in between, that he made his first big contributions to radio wave propagation. These were his explanation of 'night-effect' in direction finding observed in Egypt and Salonika, in which he invoked the existence of an upper ionized layer giving rise to a reflected wave with variable polarization characteristics, and his observation of coastal refraction which he sought to account for in terms of the properties of Zenneck surface waves.

He was thus among the first to obtain evidence of the presence of the ionosphere by the reflexion of radio waves and so began a life-long interest in the magneto ionic theory of propagation. His first work, however, on joining the Marconi Co. after the War was a classical research into the properties of earth screens for increasing the radiation efficiency of long wave aërials, followed by his analysis of the results of observations made on very long wave transmitters by K. V. Tremellon and C. M. Allnutt during a round-the-world expedition. For more than twenty years Tremellon was Eckersley's personal assistant, and his patient observational work formed the basis of the succession of papers which Eckersley wrote on short-wave radio transmission.

The last of these was on scattering from 'clouds' in the ionosphere, a subject which has since become of great practical importance in the development of the ionospheric 'forward scatter' communication system. Not only did all this work lay the foundation of much of our knowledge of the part played by the ionosphere in long-distance propagation, but it also led to many advances in technique, for example, in the field of accurate direction finding and in the measurement of field strength and polarization characteristics.

Although he would not have claimed to be a pure mathematician, he had a consummate ability to apply mathematics to physical problems. Indeed many of his experimental researches were preceded or sup-

ported by elegant analysis. He had a great interest in modern physics, especially in its quantum and relativistic aspects, and it was the knowledge so acquired that inspired some of his finest work in radio. It was the phase integral treatment of potential barriers in atomic theory that led him to his brilliant applications to ionospheric and ground wave propagation, while in the scattering of α particles he found an analogy for the scattering of radio waves as a function of wave-length, cloud size and scattering angle.

Eckersley had something of the absent-mindedness associated with genius, which was reflected in the style of his writing and made some of his papers difficult for others to read. He was thus not as well known in the world at large as he deserved to be, but in due course full recognition among scientists came with his election to fellowship of the Royal Society in 1938 and the award of the Faraday Medal of the Institution of Electrical Engineers in 1951. He was also a well known figure at international radio conferences especially at the CCIR and U.R.S.I. assemblies.

He was proud of the fact that he was a grandson of T. H. Huxley, and he was most happy in his family life, his wife being Eva, the daughter of Barry Pain, the Victorian novelist, who survives him with a son and two daughters. She is an able pianist and composer, and their home at Danbury, Essex, was often visited by distinguished musical friends. He was a delightful host, for he combined great courtesy with a delicate sense of humour, and though he did not play himself he had a great love of music.

At the time he died he had become almost completely helpless from multiple sclerosis, the first symptoms of which had appeared more than twenty years ago. In spite of increasing disability, he remained at work throughout the Second World War as scientific adviser to the Inter Services Ionosphere Bureau at the Marconi Research Laboratories, and after his retirement in 1946 he continued to work at home for several more years.

During this period he published a number of papers, his devoted wife acting as his amanuensis. There is no doubt that it was her amazing courage and cheerfulness that maintained his life for so long, and indeed it was to pneumonia during the influenza epidemic that he finally succumbed. The loving care which surrounded him during these last years was a source of inspiration to all who witnessed it.

G. M. L. STONER

Prof A O R Windaus

ON June 9 it was reported from Göttingen that Adolf Windaus had died in his eighty-third year. He had retired as professor and director of the University Chemical Laboratory at Göttingen in 1938, and was made emeritus professor and director in 1944.

Windaus was born in Berlin in 1876, educated at the Universities of Berlin and Freiburg-im-Breisgau and became *Privatdozent* in 1903. After a short period at Innsbruck, he was elected to Göttingen in 1915. He was awarded the Nobel Prize for Chemistry in 1928, and also received the Baeyer, Pasteur and Goethe Medals.

To those interested in steroids, Windaus's name will stand with that of the late Heinrich Wieland as the greatest in the period of German pre-eminence in discovery about the chemistry and physiology of these substances. Most of his publications between 1903 and 1928 were about cholesterol and described, *inter alia*, the preparation of complexes with digitonin, solanin, etc. (1909, 1918), the nature of the side-chain (1913) and the relationship to coprosterol (1916) and to the bile acids (1919). Papers also appeared on stigmaterol (1906, 1924), sitosterol (1918, 1924), hydrodeoxycholeic acid (1923, 1926), chenodeoxycholeic acid (1924, 1925, 1926) and on 'β'-phocæcholic acid (1928). All this work and much more, including some on heart poisons and saponins, was done without modern knowledge of steroid formulæ, yet Windaus's fundamental discoveries stand largely unchallenged to-day. His work on scymnol (with W. Bergmann and G. König, *Hoppe Seyl Z.*, 189, 148, 1930) was the first on the chemistry of this substance. The paper with Alfred Hess, of Columbia University, New York, entitled "Sterine und antirachitisches Vitamin" and published at the session of the Gesellschaft der Wissenschaften zu Göttingen on January 28, 1927, clearly recognized that both ergosterol and an impurity separable from cholesterol acquired antirachitic activity on irradiation with ultra-violet light. Parallel work had already begun in England (for example, I. M. Heilbron, E. D. Kamm and R. A. Morton, O. Rosenheim and T. A. Webster, *Chem. and Indust.*, 45, 932, 1926), it was energetically pursued there, and also by Windaus and his colleagues until, in 1931, success in isolating a pure vitamin D was announced almost simultaneously from Göttingen and Hampstead, London. From irradiated ergosterol, F. A. Askew, H. M. Bruce, R. K. Callow, J. St. L. Philpot and T. A. Webster (*Nature*, 128, 758, 1931) obtained calciferol, and Windaus and O. Linsert (*Liebigs Ann.*, 489, 269, 1931) vitamin D₂; these substances were later found to be identical, although the separate names were retained.

'Vitamin D₁', originally reported as pure by the German workers (*Liebigs Ann.*, 489, 252, 1931), was later proved (*ibid.*, 493, 259, 1932) to be a molecular compound of vitamin D₂ and lumisterol.

For Windaus, this was by no means the end of the vitamin D problem. Doubts as to the identity of calciferol (vitamin D₂) and the antirachitic vitamin of fish-liver oils persisted, and C. E. Bills (*Physiol. Rev.*, 15, 1, 1935) summarized evidence that the antirachitic vitamin in irradiated (impure) cholesterol and in cod liver oil (as measured in 'rat units') is more potent for chicks than the vitamin (calciferol) in irradiated ergosterol.

Windaus brilliantly recalled that J. Mauthner and W. Suda in 1896 (*Mh. Chem.*, 17, 579) had oxidized

cholesterol with chromic acid to 7-ketocholesterol, and, with H. Lottré and Fr. Schenck (*Liebigs Ann.*, 520, 98, 1935), he reported the conversion of this substance into 7-dehydrocholesterol. Irradiation of this gave a mixture from which was isolated (Windaus, Fr. Schenck and F. von Wörder, *Hoppe Seyl Z.*, 241, 100, 1936) vitamin D₃, identical with the natural vitamin obtained from tunny liver oil by H. Brockmann (*Hoppe Seyl Z.*, 241, 104, 1936) at Göttingen. Windaus's later papers were about the chemical nature of natural forms of vitamin D and the chemistry of irradiation products of ergosterol and 7-dehydrocholesterol.

Windaus's publications, which ceased in 1944, remain as an inspiring example of what a great intellect can still accomplish in scientific discovery.

G. A. D. HASLEWOOD

Dr F Busemann

DR FELIX BUSEMANN, who died on April 30 at the untimely age of fifty-one, was an outstanding authority in his chosen subject, electrical transmission, as is his brother, Adolf Busemann, one of the leading German aerodynamicists now in America. Trained at the Institute of Technology, Darmstadt, he became later assistant to the professor of electrical machine design there, and in 1934 joined the firm of Siemens Schuckert in Berlin, becoming one of a team concerned with future developments in electrical transmission. This team had as one of its assignments that of high-voltage direct current transmission. Starting with a pilot scheme between Charlottenburg and Moabit, it followed by planning the Siemens Schuckert half of the major Elbe-Berlin project. After the Second World War, Dr Busemann was chosen by the Darwin Panel and came to Britain in 1946 to report on the German work in this field.

Busemann found the social climate in Britain so akin to his temperament that he shortly accepted an offer to join the staff of the Electrical Research Association and continue his studies on d.c. transmission. These resulted in a masterly series of fourteen reports covering all aspects of the subject with the exception of valves, for the study of which facilities were lacking. He played a major part in the planning of a pilot scheme which, had it matured, would have placed Great Britain in the van of development. He was without doubt the foremost authority on high-voltage direct-current transmission in Britain, and his loss will be greatly felt.

With the temporary cessation of interest in direct-current transmission, Busemann turned his versatile mind to other aspects of transmission. Among these he devised, jointly with W. Casson, a classic programme of full-scale experiments on power-system stability (Cliff Quay), described in a paper before the Institution of Electrical Engineers last year. More recently, he had been concerned with mechanical and thermal properties of soil and utilization of power cables. To all these he brought quick appreciation of decisive factors and great facility in analysis and exposition.

Behind a natural modesty Busemann had great personal charm and humour as well as perception. He was a musician of almost professional attainment and gave much service to his church and the social activities of the Electrical Research Association. He will be remembered by all who knew him for a long time to come. He leaves a widow and two daughters.

L. GOSLAND

Miss Grace M Sickles

GRACE M SICKLES, associate research scientist in the Division of Laboratories and Research of the New York State Department of Health died on June 29 at Troy, New York. An eminent bacteriologist and virologist Miss Sickles had been a member of the Health Department since 1918 with a two year period of service (1919-20) in the Communicable Disease Laboratories of the United States Army. She was a graduate of the New York State College for Teachers and a member of the principal scientific societies in her fields of research.

Miss Sickles was associated with Dr Augustus B Wadsworth in an extensive series of investigations on the production and standardization of anti pneumococcus, antimeningococcus and antistreptococcus sera, studying, as early as 1938 the action of immune serum in conjunction with chemotherapy in experimental streptococcus infections. Some of Miss Sickles' studies of diphtheria toxin and on the antibiotic activity of micro-organisms from the soil were carried out at the Marine Biological Laboratory Woods Hole, Massachusetts.

Miss Sickles was the discoverer with Dr Gilbert Dalldorf in 1947 of the coxsackie virus. The virus was identified during a study of outbreaks of polio myelitis in New York State. It was named after the

village in which the first two recognized human infections occurred. The coxsackie group now includes more than a dozen viruses which are common sources of infection in man.

Mr W E Perry

The sudden death on June 5 of Mr W E Perry, a senior principal scientific officer at the National Physical Laboratory, Teddington, removes one of the leading figures in the field of radioactive and radiation standardization. Born in 1903 Perry took his degree from Nottingham and joined the Laboratory in 1928. He was responsible for the measurement of the National Radium Standards in 1934 and for the subsequent development of radioisotope measurements. Later as head of the Radiology Section of the Laboratory, he had charge of the work on radio isotopes, X-ray dosimetry, neutron standardization and radiocarbon dating and had an international reputation for his scientific integrity and wide knowledge in these subjects. At the time of his death, he was preparing material for the ninth International Congress on Radiology at Munich in his capacity as chairman of Committee I of the International Commission on Radiological Units and Measurements.

NEWS and VIEWS

The British Association

New President

SIR GEORGE THOMSON, master of Corpus Christi College, Cambridge, has been elected president for 1960 of the British Association for the Advancement of Science in succession to Sir James Gray. Sir George has had a distinguished career as a physicist as a man who gave outstanding service to the Atomic Energy Project in its early days and as master of Corpus Christi College. The son of the late Sir J J Thomson, he was educated at Trinity College Cambridge, obtaining a first-class degree both in the Mathematical and in the Natural Sciences Tripos. After service in France with the Army, followed by research on aeronautical problems, he was appointed to the chair of physics at Aberdeen in 1923, where he carried out the epoch making work on the deflection of electron beams by thin metal foils, thereby establishing beyond doubt the wave nature of the electron. For this work he was awarded the Nobel Prize for Physics in 1937. Between 1930 and 1952 he was professor of physics in the Imperial College of Science and Technology, London, and was chairman of the first British Committee on Atomic Energy, the Mould Committee, appointed in 1949. He has played a considerable part in the development of the subject ever since, being interested not less in its social as well as in its scientific aspects. Since his appointment to the mastership of Corpus Christi College his interest in physics has continued and he has published work on gas discharges and has been chairman of Section A (Mathematics and Physics) of the British Association. Both on account of the great distinction of his scientific work and his interest in the wider implications of scientific advance he will be a most welcome president of the British Association.

Director of the Royal Aircraft Establishment

Prof M J Lighthill F.R.S.

PROF M J LIGHTHILL, Beyer professor of applied mathematics at the University of Manchester since 1950, has been appointed director of the Royal Aircraft Establishment, Farnborough in succession to Sir George Gardner who is succeeding Air Chief Marshal Sir Claude Polly as controller of aircraft at the Ministry of Supply in October.

Prof Lighthill has made outstanding contributions in many fields of fluid dynamics as well as in more general spheres of pure and applied mathematics. His applications of the fundamentals of mathematics to various aeronautical problems have been significant and widespread. He is particularly well known for his theoretical work on jet noise, this work, which has been largely substantiated by experiment, relates the noise to the turbulence in the jet. He has always displayed a continuing interest in the practical application of his theories and has been for a number of years a member of the Aeronautical Research Council. Prof Lighthill was educated at Winchester and Cambridge, and was elected to the fellowship of the Royal Society in 1953 at the early age of twenty nine.

Royal College of Science and Technology, Glasgow

Sir David Anderson

SIR DAVID ANDERSON, who is to retire from the post of director of the Royal College of Science and Technology in December 1959, was appointed principal of Derby Technical College in 1926 at the age of 31. In 1930, he became principal of the Central Technical College Birmingham and in a period of 10 years which spanned the arduous war years he laid the foundations of the College of

Advanced Technology, designated as such by the Minister of Education in 1956. In this period, too, he became increasingly concerned with the problems of technical education at national level. This was especially true of his work as a member of the Percy Committee which reported in 1946, and greatly influenced the development of post-war technical education. He was president of the Association of Principals of Technical Institutions in 1932, and chairman of Council of Association of Technical Institutions in 1951. He was a member of Council of the Institution of Mechanical Engineers during 1941-42, 1948-50. First and foremost a Glasgow man, he was educated at Whitehill School, then at the then Royal Technical College, and served his apprenticeship with the North British Locomotive Company. He returned to the College as director in 1946, and the new engineering block, the recently opened students union, the Residential School of Management Studies at Bearsden, and the new students residences are visible signs of his vigorous leadership. He has continued to serve on a large number of bodies at national level, and was knighted in 1957. After the manner of present times, we may hope that Sir David will not retire from all public work, otherwise the constructive contributions of his incisive mind will be greatly missed.

Dr S C Curran, FRS

THE Governors of the Royal College of Science and Technology, Glasgow, have announced the appointment of Dr S C Curran as principal in succession to Sir David Anderson, the retiring director. Dr Curran studied at the Universities of Glasgow and Cambridge, graduating M.A., B.Sc., Ph.D. (Glas.), and Ph.D. (Cantab.). His early researches were concerned with radiation phenomena and new methods of detection. While at St John's College, Cambridge, and the Cavendish Laboratory, he pioneered in investigations of proton capture.

During the Second World War he shared in the successful work of the Royal Aircraft Establishment on proximity fuses and of the Telecommunications Research Establishment on the research and development of centimetre radar, having charge of one of the groups responsible for H_2S and ASV , thereafter he joined the British Mission on Atomic Weapons in the United States. At Berkeley he discovered the original form of the scintillation counter and the vacuum carbon arc. Later at the University of Glasgow he introduced the modern form of proportional counter, determining with it the form of novel beta-spectra such as that of tritium. An active research group soon grew up under his leadership.

In early 1955 he joined the Atomic Weapons Research Establishment, where he later became a chief scientist and member of the Management Board responsible for the divisions of Nuclear Research and Electronics. He also served as visiting member on the Harwell Management Board. A considerable growth of nuclear research has taken place at Aldermaston during his years there.

Dr Curran was awarded the D.Sc. and Kelvin Prize of Glasgow in 1950 and elected to fellowship of the Royal Society in 1953.

Jean Senebier (1742-1809)

JEAN SENEBIER, who died of "une cruelle maladie" at Geneva 150 years ago on July 22, 1809, is an anomalous figure in the history of botany. A clergyman untrained in the scientific method, yet possessing

the true scientific spirit, endowed with curiosity, intelligence, and industry, he had many interests: theology, botany, microscopy, physics, chemistry, meteorology, library classification. His tiresome rhetoric prevented his being appreciated by his generation. The son of a protestant tradesman of French origin, he was born on May 6, 1742, at Geneva, where he became pastor in 1765 and chief librarian in 1773. In 1792 political unrest banished him from the city for seven years. Senebier is remembered chiefly for his studies on the influence of light on vegetation. Jan Ingenhousz, an engineer of Dutch extraction, in 1779, introduced the concept of balance of animal and vegetable life by showing that plants generate dephlogisticated air. This activity was demonstrated by Senebier between 1782-88 to be confined to the green parts of plants which, under the influence of sunlight, convert fixed air (carbon dioxide) into dephlogisticated air (oxygen). His "*Mémoires physico-chimiques sur l'influence de la lumière solaire pour modifier les êtres des trois règnes de la nature*" in three volumes were published in 1782. The first to formulate a theory, in strictly chemical terms, of vegetable nutrition in his 'tediously prolix' (Sachs) five-volume "*Physiologie végétale*" (1800), he stimulated his fellow Genevan, Nicholas Théodore de Saussure, to write his "*Rocherches chimiques sur la végétation*" (1804), which was to eclipse his own work. He was a corresponding member of the Institut de France and of the Royal Academy of Turin.

International Commission on Higher Education in Nigeria

SIR ERIC ASHBY (vice-chancellor of the Queen's University of Belfast and master-elect of Clare College, Cambridge) returned from Lagos on May 7, after attending the inaugural meeting of the International Commission on Higher Education in Nigeria. The Commission (*Nature*, 183, 1231, 1959), with Sir Eric Ashby as chairman, consists of two other United Kingdom members, Dr J. Lockwood (master of Birkbeck College) and Dr G. E. Watts (principal of Brighton Technical College), and three American members, Dr Frank Koppel (dean of the Graduate School at Harvard University), Dr Eric Walker (president of Pennsylvania State University) and Prof H. W. Hannali (associate dean of agriculture, University of Illinois). The Nigerian members are Shettima Kashim (formerly Federal Minister of Social Services, chairman of Nigerian College of Technology), Prof K. O. Diko (vice-principal and professor of history, University College, Ibadan) and Dr S. D. Onabamiro (senior research fellow in parasitology, University College, Ibadan).

Sir Eric Ashby, speaking at the inauguration meeting in Lagos on May 4, described the decision to set up a Joint Nigerian-United States-United Kingdom Commission as a "Landmark in educational history" as this was the first time that such an international group had been appointed to study higher education in Nigeria. He assured the meeting that the Commission would be able to recommend some of the educational needs of the first twenty years of Nigerian independence could be met, and that it would do its best to prepare for Nigeria something which could be turned into action.

'Procynyl' Dyes

Imperial Chemical Industries, Ltd., has introduced 'Procynyl' dyes, a new class of disperse dyes. It is claimed that the initial four 'Procynyl' dyes display

on nylon and other polyamide fibres the desirable attributes of the established disperse dyes—good levelling, good coverage of irregular-dyeing yarns, good compatibility in admixture, good temperature range properties and good penetration. They are applied in a similar manner. The essential difference is that the 'Procynyl' dyes are applied initially under slightly acid instead of neutral conditions, and that dyeing is completed by an alkaline fixation stage during which certain reactive groups in the Procynyl dye molecules react chemically and irreversibly with the amino or amide groups in the polyamide fibre and so produce dyeings of high wet-fastness. All forms of nylon and other polyamide fibres of both the staple fibre and continuous filament types and including woven piece goods, knitted piece goods and hosiery can be dyed satisfactorily with the new dyes, which may be applied, as necessary, on the jig (covered jigs for preference) on winches, in paddle dyeing machines and in circulating liquor machines. The initial four Procynyl dyes—a yellow an orange a scarlet and a blue—permit an extensive range of shades to be produced because of the wide inter-compatibility of the new dyes.

Only slight or negligible reaction takes place between 'Procynyl' dyes and acetate and tricotone rayons, for which the new dyes are not expected to be of much immediate interest although the wet-fastness achieved is generally better than with normal disperse dyes. With the exception of 'Procynyl Yellow G', the dyes are of minor importance on 'Terylene' and other polyester fibres. On 'Acrilan' polyacrylonitrile fibre, although 'Procynyl' dyes build up well to give heavy shades of very high wet-fastness which results from the reaction between the dye and the basic groups in the fibre, only the yellow is of particular interest, the remaining dyes giving shades of low light fastness. On acrylic fibres not modified by the incorporation of basic substances they display only limited build up.

British Ceramic Research Association

Mellor Library

THE new library of the British Ceramic Research Association—the Mellor Library—was opened at Stoke-on-Trent on June 16 by Mr Frank West, vice-president of the Association and a lifelong friend of the late Dr J W Mellor, in whose honour the library has been named. Dr Mellor, the well-known physical chemist, turned his mind to problems of the ceramic industry Wedgwood, a century and a half previously had transformed a craft into an industry, Mellor during the first three decades of the present century did outstanding service to that industry by giving it the basis of sciences that had hitherto been largely wanting. As head of the Pottery Department of the North Staffordshire Technical College Mellor taught a generation of pottery managers, as first director of research of the British Refractories Research Association (the forerunner of the British Ceramic Research Association) Mellor initiated research at a time when industrial research was a novelty. But perhaps he is best known as the author of the "Comprehensive Treatise on Inorganic and Theoretical Chemistry."

Educational Research

THE third issue of *Educational Research*, the journal of the National Foundation for Educational Research in England and Wales, contains articles on the teaching of mathematics, the ability to teach the effect

of environment on intelligence, school guidance services and a comparison of attainments in different types of primary school. There is also a selected and annotated bibliography of works on the curriculum of the secondary school (Newnes Educational Publishing Co., Tower House, Southampton St., Strand, London, W.C.2 5s 6d). In the article on the teaching of mathematics, Mr J B Biggs discusses the distaste for school mathematics so commonly reported. His conclusions evaluate the relative effect of basic personality and specific likes and dislikes particularly in the case of the maladjusted child. Many so-called lazy children are seen to have found an initial block to their number learning because of their temperament. This is heightened by accusations of laziness and consequent unimaginative driving by some teachers. The implications of this and the other stimulating conclusions are important to the teacher who might well ask himself why there is no similar anxiety concerning English.

A New Geological Documentation Service

THE wealth of information available constitutes a serious problem for the future of the research in the Earth sciences. Before 1939, published work could be covered by giving about one thousand references a month. At present, the Service d'Information Géologique of the Bureau de Recherches Géologiques, Géophysiques et Minérales indexes monthly more than 3,000 references, and it is estimated that 5,000 references should be given to ensure complete coverage of the field. The situation is complicated by the number of works now appearing in little-known languages and by the launching of new periodicals and special publications. Faced with this problem, the Service d'Information Géologique of the Bureau de Recherches Géologiques, Géophysiques et Minérales, which has taken over and expanded the work of the Centre d'Etudes et de Documentation Paléontologiques, has set itself the task of providing an extended and rapid service of basic geological information. The Service d'Information Géologique scans every week about 3,500 periodicals, more than 200 of which are published in Russian. The references are typed in the original language or if they are not in Latin characters, are translated, usually into French, then are then classified in 1,200 sections under twelve main headings (mineralogy, petrography, stratigraphy, tectonics, geophysics, geological activities, geological phenomena, applied geology, general palaeontology, biology, botany and zoology). The work is of course carried out under the supervision of scientists. Each reference is indexed by title and by content. The average number of indexes to each abstract card is five.

Central Advisory Water Committee

ON the expiry of the first period of appointment, the Minister of Housing and Local Government Mr Henry Brooke has reviewed the composition of the Central Advisory Water Committee and made various re-appointments and new appointments. The membership of the Committee is drawn from the major interests concerned with water, for example, water supply, industry, scientists, agriculture, river boards. The Minister is chairman of the Committee and the vice-chairman is the Parliamentary Secretary, Mr J R Bevin. Since its reconstitution in 1955 the Committee has published reports on the demand for water in England and Wales on information on water resources and on the law dealing with the disposal of trade effluents.

Seismological Association Meeting in Toronto

THE report of the meetings of the Section for Seismology and the Physics of the Earth's Interior, prepared by the associate secretary, Dr Markus Bath, of Sweden, has recently been published (pp 448 Strasbourg Bureau Central International de Séismologie, 1958). Most of the subdivisions into which this subject may be divided were discussed in the twenty-two sessions. Detailed reports of these meetings, the presidential address by Prof K E Bullen, of the University of Sydney, the report of the meeting of the European Seismological Commission, the Committee of the International Seismological Summary and the Committee for the International Geophysical Year are included. In addition, there are seismological reports from thirty-four countries, and the resolutions adopted at the assembly. The whole covers some 455 quarto pages. At the conference, ten sessions were devoted to seismology alone, six to joint meetings with the Association of Volcanology and two to joint meetings with the Association of Geodesy. It was at an extra session at Toronto that Prof K E Bullen announced that the U.S. Atomic Energy Commission had released information concerning the time and place of a future underground nuclear detonation in Nevada, so that seismologists could prepare to participate in the recording. The International Geophysical Year Committee discussed particularly the recording of earthquakes with epicentres in the arctic and antarctic regions, and it is noteworthy that M E Guyot is proceeding with the preparation of a seismological dictionary which it is hoped will be published without delay.

Soil Survey of Great Britain

THE soil survey of Great Britain, with headquarters at Rothamsted, will occupy many years, and reports are to be published as each county is completed. The magnitude of the task can be realized from the memoir on Anglesey (Agricultural Research Council Memoirs of the Soil Survey of Great Britain—England and Wales. The County of Anglesey. Soils and Agriculture. By E Roberts. Pp viii + 116 + 11 plates. London: H.M. Stationery Office, 1958, 10s net), which includes also a small proportion of Caernarvonshire, nearly fifty soil series, which are the mapping units, are identified and described. Anglesey is relatively flat, but there are considerable variations in the land surface due to the rugged outcrops of the Mona complex, the sharp escarpment of the Carboniferous limestones, the igneous rocks, wind-blown sands and glacial features. The varying thickness of the boulder clay has contributed to the irregular undulations of most of the fields.

Classification and mapping of the soils are based on the soil profile, since it reflects the action and balance of the many processes that have led to its formation, drainage has a profound effect, and is taken into account in the classification. Although familiar to soil scientists and to many advisory officers, the subject is new to workers in related subjects, and to farmers. The Soil Survey of Great Britain will be the foundation for a planned approach to fertilizer and cropping problems for many years, and such reports will have to be studied, and the maps referred to frequently. The one inch to the mile soil map that is provided may prove too small for reference to some individual farms on or near the margins of the soil areas, but a 6 in map is available for reference at Rothamsted.

Grassland Productivity

"The Measurement of Grassland Productivity" was the subject of the sixth Easter School in Agricultural Science which was held at the University of Nottingham School of Agriculture, Sutton Bonington, during April 13–16, and was organized by Prof J D Ivins. Twenty papers were read, primarily concerned with techniques of grassland evaluation. Assessment of productivity from the botanical point of view, in terms of animal production, the consumption of herbage by grazing livestock and grassland productivity on a farm scale were considered. New varieties of herbage plants have been produced and then requirements have been explored to a great extent. New techniques have been developed which have resulted in vast increases in the production from grassland, but a constant problem and hindrance to development has been—and still is—the lack of methods which may be used with validity to measure and compare grassland productivity. Some 140 members from Britain and overseas exchanged experiences and ideas and discussed the limitations and applications of techniques of measuring the productivity of grassland. The proceedings will be published.

Safety in Mines Research

THE thirty-sixth annual report on Safety in Mines Research (pp 81 + 4 plates. London: H.M. Stationery Office, 1958. 5s net) is a general review of progress in the year 1957 of the Safety in Mines Research Establishment of the Ministry of Power. The report describes research undertaken in the general fields of explosives and blasting devices, explosion hazards, breathing apparatus, fire hazards, engineering and metallurgy, dust control and pneumoconiosis hazards, and in certain other fields, together with a record of testing services carried out by the Establishment. A significant feature of some aspects of the work is the active co-operation and interchange of results with kindred establishments in France, Germany and Poland. More than ninety topics are discussed, it is difficult to select individual topics for special mention, but perhaps attention may be directed to the work reported on the fluid mechanics of coal dust explosions, a subject of interest to all concerned with fires and explosions due to organic dusts. There are, in fact, many topics reported which are of interest and importance to several industries in addition to the mining industry, including breathing apparatus, engineering and metallurgical problems of importance in conveying, winding and supports, and the study of dusts and of pneumoconiosis.

Morbidity Statistics from General Practitioners

IN the series of Studies on Medical and Population Subjects, the first volume of morbidity statistics collected from general practitioners has recently appeared (General Register Office. Studies on Medical and Population Subjects No 14. Morbidity Statistics from General Practice, Vol 1 (General). By Dr W P D Logan and A A Cushion. Pp iv + 174. London: H.M. Stationery Office, 1958. 15s 6d net). A number of practitioners agreed to keep records of all consultations with patients on their list, and the General Register Office went to considerable trouble to obtain the correct population at risk to which these consultations could be related. While the practices were not chosen as a representative sample of the total population, this is the

first time that a survey has been taken, and that data showing the load on general practitioners have become available on this scale. The present publication shows consultation rates and rates of patients consulting for different age and sex groups and different diseases. It is expected that a further volume which will contain figures on occupational morbidity will be issued in the future.

Mammals of the Belgian Congo

A PAPER by J. Verschuren on the ecology and biology of the larger mammals of the Garamba National Park in the north-east of the Belgian Congo forms the ninth fascicle of the results of H. de Sager's expedition for the exploration of the park (Exploration du Parc National de la Garamba Mission H. de Sager Fascicule 9 Écologie et Biologie des Grands Mammifères (Primates, Carnivores, Ongulés) Par Jacques Verschuren Pp 226+2 planches Bruxelles Institut des Parcs Nationaux du Congo Belge 1958). In the region studied the larger mammals are much more difficult to observe than in East Africa owing to the much denser vegetation in which they seek refuge, but the author has made good use of the two years that he was in the field and has collected much valuable information about their biology. After a short introduction describing the country and the methods employed the work is arranged systematically, and each species is dealt with under the headings: particulars of specimens examined, local names, geographical distribution, systematics and morphology and ecology and biology. For most species the last section is by far the largest and is full of carefully recorded observations of the greatest interest. Fifty-one species are dealt with, distributed among the Primates, Pholidota, Carnivora, Tubulidentata, Proboscidea, Hyracoidea, Perissodactyla and Artiodactyla. The author adds that his lengthy experience of mammals in the wild has convinced him of the invalidity of many of the innumerable forms, subspecies, and races that have been so profusely described by some writers—a remark that will be heartily endorsed by other field zoologists. The value of the paper is enhanced by a large number of photographic illustrations including two plates in colour.

Collision Broadening of Spectral Lines

COLLISION broadening is an important process in the formation of stellar absorption lines and collision shifts have been discussed as a possible explanation of that part of the red shift of solar lines which is unaccounted for by the Einstein gravitational shift. W. R. Hindmarsh (*Mon. Not. Roy. Astron. Soc.*, 119, 11, 1959) has recently reported the results of the first of a series of measurements of collision effects in atomic spectra. The collision shift and broadening of the neutral calcium line $\lambda 4227 \text{ \AA}$, due to an external pressure of helium, have been measured. The line was formed in absorption by passing white light through calcium vapour in the presence of helium at various pressures less than one atmosphere. The half-intensity damping width of the line was found to be $1.72 \times 10^{-10} \text{ cm}^{-1} \text{ per atm. cm}^2$ of helium, and the shift $0.05 \times 10^{-10} \text{ cm}^{-1} \text{ per atm. cm}^2$ towards the violet. The ratio of broadening to shift on the Lindholm theory is 2.76, and the shift is predicted to be towards the red. The observed ratio is much larger and the observed shift is in the opposite direction. This discrepancy must be due to the involvement of the short range repulsive forces

between calcium and helium atoms as well as the long range van der Waals forces. Hindmarsh also shows that the collision shift of the calcium line is a negligible component of the solar red shift and cannot account for the difference between observed and predicted solar red shifts. In the second paper following the above W. R. Hindmarsh and K. A. Thomas show that for two argon lines the collision shifts are in reasonable agreement with the Lindholm theory.

Hot Laboratory Equipment

'Hot Laboratory Equipment' is a revised and enlarged second edition of the 'Hot Laboratory Catalogue', which constituted the major portion of 'Chemical Processing and Equipment' (TID 5278) published by the U.S. Atomic Energy Commission as one of the several volumes for the 1955 International Conference on the Peaceful Uses of Atomic Energy. The new edition (pp. vii+429, Washington D.C. Government Printing Office 1958, 2.50 dollars) which is fully illustrated, contains descriptions of facilities, equipment and accessories for handling moderate to large amounts of radioactive materials. It lists 229 items compared with 126 in the first edition, and includes newly developed items as well as items omitted for various reasons from the first edition. Acknowledgment is made wherever possible to the organization responsible for the development of the particular equipment described. Most of the equipment listed was developed by national laboratories or contractors to the Commission but some were developed by private firms. The contents is confined to hot laboratory equipment produced in the United States but the reader is referred in the preface to two British publications (*Remote Handling Equipment* by A. Apperly, Atomic Energy Research Establishment F/R 1291, and *Radio Isotope Instrumentation and Accessories* by D. Taylor and A. G. Pearce, Scientific Instrument Manufacturers' Association, 1955) for information on similar equipment available in Great Britain.

Textiles and Dyes at the University of Leeds

THE eighty-fourth report of the Textile Industries and Dyeing Advisory Committee on the work of the Departments of Textile Industries and Colour Chemistry and Dyeing in the University of Leeds (pp. 47, Leeds: The University 1959) covers the session 1957-58, in which applications for admission greatly exceeded places and very full programmes of teaching and research were maintained. In the Textile Industries Department, full-time students numbered 351 and in that of Colour Chemistry and Dyeing 59. Lists of publications are included. In textile physics work continued in X-ray diffraction, electron microscopy, infra-red absorption and sedimentation in the ultracentrifuge. A second electron microscope was installed. In textile chemistry a method of producing a permanent lustre on all wool fabrics has been developed and the chemical mechanism of permanent set, especially that obtained with sulphite-bisulphite solutions, was re-examined. Work on the effect of variations in the nature of the keratin in the assessment of wool quality continued. The constitution of some sun pigments which may be involved in the staining of wool, the surface activity of steroids and proteolytic degradation of cholesterol are being studied and a brief examination of the dielectric properties of lanosterol indicated its suitability for use in impregnated paper capacitors.

In textile engineering good progress is reported in the analytical study of loom noise and in a study of the drying of textiles. In textile technology, work on the chemistry and practice of finishing fabrics made from both wool and man-made fibres continued and on the measurement of yarn irregularity. The chemical properties of pigmented wool, the action of concentrated sulphuric acid on wool, the removal of compounds of high molecular weight from textile materials and the degradation and yellowing of nylon were also studied.

In the Department of Colour Chemistry and Dyeing the course of the changes which occur in the reaction of aromatic carbonyl compounds with basic substances was examined, a study of stilbene-quinone and its derivatives was completed, and work on elimination of groups from vat dyes on reduction and on the reactions of sulphonic acids with azo compounds and azines continued. A group of diazonium salts soluble in benzene was prepared, and a study of the interaction of aminoanthroquinones and aminofluorenes with nitrobenzene and α -nitronaphthalene was completed, as well as work on the vapour pressure and absorption energies of some anthroquinone and azo dyes. The influence of the acetyl value of acetate rayon on the rate of dyeing and affinity for disperse dyes is being studied.

Journal of Nutrition

DR RICHARD H. BARNES, dean of the Cornell University Graduate School of Nutrition, Ithaca, New York, has been appointed editor of the *Journal of Nutrition*. He succeeds Dr George R. Cowgill of the Yale Nutrition Laboratory, who has served as editor for twenty years. Dr Cyril L. Comar, director of the Laboratory of Radiation Biology, New York State Veterinary College, has been appointed associate editor. The appointments became effective July 1, 1959. The editorial offices of the *Journal of Nutrition* are being moved from Yale University to the Cornell University campus. Manuscripts should be sent to Dr Barnes at the Graduate School of Nutrition, Savage Hall, Cornell University, Ithaca, New York.

Nature Conservancy Awards for 1959

THE Nature Conservancy announces the following awards of research studentships for postgraduate training in ecology, tenable for periods up to three years at the universities shown: *Botany* J. K. Marshall (Cambridge), D. P. Nicholas (Liverpool), W. J. Roff (Cambridge), J. T. R. Sharrock (Southampton), D. T. Streeter (London), *Zoology* M. L. Clark (Leeds), E. R. Creed (Oxford), J. M. Edington (Durham), C. J. Henty (Oxford), J. B. Nelson (Oxford), G. C. Phillips (Oxford), *Geography* I. G. Simmons (London).

University News

Edinburgh

PROF. A. D. RITCHIE, professor of logic and metaphysics in the University of Edinburgh, retires on September 30, his long and distinguished career was mentioned in reviewing his recent book, "Studies in the History and Methods of the Sciences" (*Nature*, July 4, p. 4). Prof. E. E. Harris, formerly professor of philosophy in the University of the Witwatersrand, has been appointed acting head of Prof. Ritchie's Department for one year.

Swansea

THE following appointments have been made in the University College of Swansea for the session 1959-

60, Dr J. R. Cross, superintendent of the Chemistry Laboratories, Miss Glenys Thomas, map curator and cartographer in the Department of Geography, Mr P. W. Davies, assistant lecturer in metallurgy, Dr H. E. Evans, lecturer in engineering, Mr B. W. Preece, assistant lecturer in engineering.

Announcements

MR. WALTER GARNER, formerly chairman of the Yorkshire Section and at present chairman of the London and District Section of the Textile Institute, and Dr A. R. Urquhart, honorary secretary of the Institute and an assistant director of the British Cotton Industry Research Association, have been awarded the Service Medal of the Textile Institute.

PROF. H. MARK, director of the Polymer Research Institute of the Polytechnic Institute of Brooklyn, New York, will deliver the Fourth Baekeland Memorial Lecture under the title "Recent Progress in Polymer Chemistry". The Lecture will be delivered on October 22 at the Royal Institution, Albemarle Street, London, W.1.

THE International Commission on Zoological Nomenclature has been given accommodation in the British Museum (Natural History). This will greatly facilitate the work of the Commission by reason of the unique library facilities and wide range of specialist advice available. Correspondence should in future be addressed to Mr N. D. Riley (Honorary Secretary), International Commission on Zoological Nomenclature, c/o British Museum (Natural History), London, S.W.7.

THE second session (1959-60) of the Welsh Soils Discussion Group will open with a meeting in the Department of Agricultural Chemistry, University College, Bangor, on October 28. The subject for discussion will be "Mineralogical Aspects of Soil Science", the introductory speakers will be Dr F. Smithson and Mr R. I. Davies (Bangor) and Mr. D. F. Ball (Nature Conservancy, Bangor). Further information can be obtained from Mr J. A. Taylor, Geography Department, University College, Aberystwyth.

THE Scottish Conference on "Relationships in Industry: Some Changing Concepts of Management", which is being organized jointly by the British Institute of Management and the Ministry of Labour, will be held at Gleneagles Hotel during October 23-24. It will be opened by Sir Alexander Fleck, chairman of Imperial Chemical Industries, Ltd. Further information can be obtained from the British Institute of Management, Management House, 80 Fetter Lane, London, E.C.4.

IN November 1859 Charles Darwin published "The Origin of Species" and Queen Victoria granted the Royal Title to the Royal Society of Victoria. To mark these two centenaries, the Society is organizing a symposium on the Evolution of Living Species, to be held in Melbourne during December 7-11. Dr Ernest Mayr of the United States will be the guest speaker. Further information can be obtained from the Honorary Secretary, Royal Society of Victoria, 9 Victoria Street, Melbourne, C.1, Victoria.

REFERRING to the review in *Nature* of June 27, p. 1766, Messrs Chapman and Hall state that the present American price of Cox's "Planning of Experiments" is 7.50 dollars.

MOLECULAR AND ATOMIC MOTIONS BY RADIO-FREQUENCY METHODS

MAXWELL-A.M.P.E.R.E. CONFERENCE

A JOINT meeting of the Colloque A.M.P.E.R.E (Atoms et Molécules par Etudes Radio Electriques) and the British Radio Frequency Spectroscopy Group was held during April 1-3 at Queen Mary College, University of London. The meeting was attended by more than two hundred scientists, mostly from the British Isles but with strong representation from France, Holland, Switzerland and the Eastern European countries in particular. The subject for discussion at the Conference was, 'Molecular and atomic motions in liquids and solids by radio frequency methods'. In the tradition of the A.M.P.E.R.E meetings the subjects covered were, dielectrics, nuclear magnetic resonance, quadrupole magnetic resonance and electron spin resonance. However, the range of the papers was constrained somewhat more than has been usual at the A.M.P.E.R.E conferences by the specification of a subject for discussion, albeit rather widely interpreted.

The forty four papers presented showed the power and range of the radio-frequency methods in studying molecular and atomic motion and there was an impressive consistency and similarity in the information produced by the very different experimental methods. It was regrettable that time did not allow the inclusion of mechanical and ultrasonic absorption measurements although these received mention in several of the papers.

Since many people versed in one discipline attended lectures in another, the occasion was a suitable one for having a general introductory lecture in each subject, and these were given by Prof H. Fröhlich (Liverpool) on "Dielectric Theory", Dr J. G. Powles (London) on "Motional Effects in Nuclear Magnetic Resonance" and by Dr M. Buylo Bodin (Grenoble) on "Motional Effects in Pure Quadrupole Resonance". Even so, many of the discussions became extremely technical and specialized and the difficulty in having a meeting on a subject which cuts across the traditional interests and compartments of science was apparent. This difficulty is a common one in conferences these days although highly specialized discussion is said to be evidence of 'immaturity' of a subject. It is regrettable that the cross fertilization which should be brought about by conferences such as this one is so difficult to achieve. It is therefore very valuable to have organizations 'd'Informations mutuelles' such as the Colloque A.M.P.E.R.E and the British Radio Frequency Spectroscopy Group the membership of which cuts across the traditional disciplines and contrasts with the extreme specialization of many organizations.

It was a source of great sorrow to all present, and particularly to the writer, that Prof. Freymann (Paris), the inspiration of the Groupement A.M.P.E.R.E, was unable to be present owing to illness, and that this should be the first A.M.P.E.R.E Conference he has missed.

The conference overcame in large measure the difficulties occasioned by the fact that it was held outside France for the first time (apart from a foray to Geneva in 1957) and was well attended by French scientists. Although some 50 per cent of the papers

were presented in French, the British members appeared to survive the ordeal without severe discomfort, and it may be that the teaching of French in our grammar schools is not as ineffective as is commonly supposed. The language difficulty was lessened by the provision of pre-prints of most of the papers.

It would obviously be impracticable to mention all of forty four papers and a brief summary only will be presented in an attempt to give some idea of the scope of the conference.

The conference was opened by Prof H. Fröhlich, who gave a masterly summary of the present situation in the theory of dielectrics, the main point of which was that the whole of the general theory has been worked out. The continuing appearance of papers on 'general theory' are no more than mathematical exercises, and whether these results are correct or not they are irrelevant. This point of view was undoubtedly novel to many present. He elaborated his position by discussing the whole field of dielectric loss in which he distinguished four types all but one of which are well understood. He was particularly concerned with the extent to which the theory can be dealt with macroscopically, which is of first importance because of the long range nature of dipolar forces, and with the number of independent parameters required for an understanding of the phenomena involved. He did point out nevertheless that a great deal of work remains to be done in the theory of dielectrics but that this should be concerned with the detailed interpretation, using models and so forth and in the search for information about materials and processes.

This lecture led on naturally to the more detailed discussion of a number of papers on dielectric loss in liquids and solutions, which depends in large measure on molecular properties and in which the 'model' aspect was very evident.

J. D. Hoffman (National Bureau of Standards, Washington) introduced a session on solids with an account of his work on systems having multiple relaxation times leading to bimodal, or even multimodal, loss curves which he explains in terms of multiple minima in the energy as a function of the orientation of a dipole. A paper by H. Gränicher and C. Jaccard (Zurich) summarized the present position in the interpretation of the dielectric properties of ice. B. Szegedi (Liverpool) described his recent work on a so far unobserved librational absorption process which should be found in crystalline long-chain substances.

There were a number of papers on the dielectric properties of systems in which water or a gas was adsorbed on materials such as silica gel.

The session on nuclear magnetic resonance was opened by J. G. Powles (London) who gave a summary of motional effects which can be studied by nuclear magnetic resonance including numerous examples of the various types of effect which may occur. He pointed out that examples of many of these would be found in the following papers but gave a number of extra ones in order to provide a balanced picture of the potentialities of the method.

two soils in pots. The specific activity of calcium absorbed by barley and ryegrass fell steadily during growth owing to a slow equilibration with forms of calcium other than exchangeable calcium. As roots locally depleted supplies of labile calcium, more calcium came into circulation. Exchangeable and available calcium can no longer be regarded as synonymous, and the latter is affected by the activities of plant roots.

Dr R. Scott Russell (Agricultural Research Council Radiobiological Laboratory) directed attention to different steps in nutrient absorption by roots and stressed that the effective area of absorption was restricted to a region near the apices. The availability of a nutrient to a plant may be influenced by interactions with other ions either by competition or by physiological changes. Dr Scott Russell referred to work which suggested that the individual root-absorption characteristics of different crops influenced the apparent availability of a nutrient such as phosphorus in a soil.

The probable parts played by micro-organisms were described by Mr J. S. Waid (Levington Research Station, Ipswich), who stressed that much of the evidence was circumstantial and required further substantiation. Organisms are known to be able to increase the water solubility of nutrients by oxidation or reduction, and by the decomposition of organic materials, the availability of nitrogen is intimately bound up with biological processes. Soil organisms may compete with roots for soluble nutrients especially when stimulated by supplies of organic materials, some of which may be provided by the roots themselves, production of carbon dioxide or toxins may affect the physiological activity of plant roots.

Dr G. W. Cooke's paper (Rothamsted Experimental Station) described the problems of assessing the nutrient status of a soil for advisory purposes.

here the criterion is the probable economic response of various crops to fertilizer dressings, and in this field soil analysis has not made much progress. The results generally distinguish between the broad levels of nutrient status for phosphorus and potassium, but in order to avoid crop failure in the exceptional cases the overall application of these fertilizers is about double the amount that is economically justified. The assessment of the nitrogen status of soils is even more uncertain, and there is an acute need for the development of fresh analytical techniques tested against field trials. Dr Cooke suggested that a more successful approach might lie in the use of soil analysis for 'fertility control' whereby a record was maintained of the fertility status of a soil so that warning was given of abnormalities before they became acute.

In the open discussion which followed these papers the following points were among those made.

Correlation between soil analyses and field responses is poorer in tropical and other under-developed areas than it is in Britain, yet the need for reliable soil tests is even greater. Different speakers stressed the importance of studying the anomalous soils in order to discover which factors affecting the availability of nutrients have been neglected. Analysis should not be divorced from examination of profiles since often these showed some physical property which meant that, while nutrients might be available in the chemical sense, they were inaccessible to plant roots.

The value of plant analysis in relation to fruit crops and forestry was mentioned, by this means it may be easier to recognize an interaction effect which is not revealed by soil analysis. Some progress was also reported on the development of techniques for determining the nitrogen status of soils: this seems to be greatly affected by re-wetting of air-dry samples.

D. V. CRAWFORD

AHMEDABAD MILLOWNERS' TEXTILE INDUSTRY'S RESEARCH ASSOCIATION

A TEXTILE research laboratory, created and sustained by the co-operative effort of the industry and the Government of India, was envisaged by the Ahmedabad Millowners' Association as early as 1944. In 1947, the Ahmedabad Textile Industry's Research Association was registered with a membership of seventy-one mills. Ahmedabad thus became the proud pioneer in establishing a co-operative research centre for the cotton textile industry in India.

The Association started functioning in 1949, and its impact was soon felt by the industry in and around Ahmedabad. It became clear to the original members that the benefits accruing from research could with advantage be placed at the disposal of the industry on a nation-wide basis. With this object in view, the constitution of the Association was suitably amended so that mills outside Ahmedabad could become members and enjoy the same research benefits as the original founders. The present strength of members including all categories stands at eighty-eight mills and allied concerns, comprising thirty lakhs of spindles and sixty-three thousand looms—roughly one-third of the Indian cotton textile industry.

The policies of the Association are decided by an autonomous body known as the Council of Adminis-

tration. At present, the twenty-member Council is made up of representatives of management, nominees of the Government of India, the director and secretary of the Association as well as directors of other research organizations, and co-opted scientists. The Textile Commissioner is one of the nominees of the Government of India. Shri Kasturbhai Lalbhai has been the chairman of the Council from its inception.

The composition of the Council ensures a balanced and co-ordinated research policy which takes into account similar efforts by other textile research institutions and national laboratories. Further links with Government and with national research in related spheres have been established through the Ministry of Scientific Research and Cultural Affairs.

The Association began modestly in 1949 in three rooms in the Mafatlal Gazalbhai Science Institute. The foundation stone of the present building, which is housed on a 50-acre campus to the west of Gujarat University, was laid by Sardar Vallabhbhai Patel in November 1950. The building was completed towards the end of 1953 and formally declared open by Shri Jawaharlal Nehru in April 1954.

The laboratories of the Association are equipped with instruments for research in textiles and allied fields. Some of these instruments have been designed and fabricated there. The physics laboratory has equipment for studying the structure and physical and mechanical properties of fibres, yarns and fabrics. The chemistry laboratory has, in addition to the usual facilities for analysis of textile materials, a unit processing section equipped for the treatment of samples of yarns and fabrics through processes such as bleaching, dyeing, printing and finishing. The pilot mill is a versatile unit and its machinery offers a wide range of processing sequences in spinning, weaving and chemical processing. The workshops are equipped for the dual purpose of servicing mill machinery and of designing, fabricating and servicing laboratory instruments.

The Association owes its success in large measure to the enthusiasm of its workers. Most of these workers have been recruited from universities and, initiated into specialized fields of industrial research. When necessary, training has been supplemented by periods of study in overseas institutions. Technical assistance schemes such as the Point Four Programme, the Colombo Plan and the Imperial Chemical Industries Fellowships have been of great value. From a small group of about twenty-five workers in 1949, the Association has developed into an organization with a total strength of 200, which is made up of 75 scientists and technologists, 25 administrative workers, 40 skilled operatives and 60 service personnel.

The services of a number of foreign specialists have been secured from time to time with the assistance of organizations like Unesco and the International Labour Organization, in 1950 the Association was recognized by Gujarat University as a teaching centre for postgraduate research. At present most of the research students are awarded scholarships or fellowships by the Government of India, the Council of Scientific and Industrial Research, Gujarat University and the Association.

In a technologically under-developed country, it is often the path of least resistance to apply to one's own use the findings of more advanced countries. During the early days, the Association emphasized the application of scientific and technical knowledge already available to the problems of the industry. This practice of helping the industry to implement the findings of research has paid rich dividends and constitutes one of the main activities of the Association at present. In the process, industry has become wide awake to the potentialities of original research and has cordially welcomed the Association's efforts.

While being primarily a research organization the Association tries to help industry in other ways. Training in various skills, such as management and supervision, statistical methodology and testing procedures, is given to the staffs of member mills. Such trained personnel not only become better equipped for their work, but also help in securing more effective implementation of the Association's programmes. Often, they form the nucleus of research and training groups in their own organizations.

GLASSHOUSE CROPS RESEARCH INSTITUTE

THE annual report of the Glasshouse Crops Research Institute for 1957* shows that, although full facilities are not yet available, the physical development of the Institute has made good progress and some of the major problems associated with commercial glasshouse practice have been investigated. Physiological studies of the growth of tomatoes have continued, and practical problems of plant spacing and pruning have received attention. Previous studies at Chesham and the Institute have shown that retention of lateral branches below the first truss, on widely spaced plants, of the variety 'Potentato' gave a yield nearly three times as great as on single stemmed plants. It was of importance to discover whether this constituted an increase in yield per unit area of glasshouse space, the factor of most concern to the grower. This has been investigated in preliminary experiments by comparing the yields from plants having no side shoots and plants in which side shoots below the first truss had been allowed to develop. Three different spacings between the rows were used. The greatest yield per unit area was obtained from single stemmed plants at the two closest spacings, namely, 2 ft and 3 ft, although multistemmed plants at 3 ft and 4 ft spacings had the greatest mean weight of individual fruit. No treatment had any effect on weight per unit area of early fruit.

A review of the literature on spacing of tomato plants in commercial cultivation, included in the report, shows that there is no simple answer to the

question of optimal planting density for maximum yield. It is thought that this may be because sufficient attention has been given to possible interactions between planting density and watering and manuring. The study of the composition of the tomato fruit has been continued by the Chemistry Department, especially in relation to variety and state of ripeness of the fruit, with special reference to fruit quality and ripening disorders. It was concluded that the latter, evident by their effects on the outer fruit wall, were also related to the composition of the inner portion of the fruit. Further investigations were made of the changes during ripening. The acidity in the wall increased from the green stage to the first appearance of yellow pigmentation, but there was no consistent trend as ripening proceeded. This was in contrast to the situation in the inner portion of the fruit, where acidity decreased and sugars (mainly glucose and fructose) increased. The concentration of soluble solids in the expressed sap of the tomato varies considerably in relation to fruit quality and variety. These investigations will be facilitated by the demonstration that measurement of refractive index by a simple hand refractometer gives a reliable indication of total dissolved solids.

Work on urea-formaldehyde compounds as slow acting nitrogenous fertilizers has been concluded and a report gives the relative merits of the several compounds tested. Liquid feeding of tomatoes is of considerable topical interest, especially in connexion with automatic irrigation and research on this problem has been resumed. Magnesium deficiency

* Glasshouse Crops Research Institute. Annual Report 1957. Pp. 161. (Littlehampton: Glasshouse Crops Research Institute 1958.) 10s.

in glasshouse tomatoes is common, and preliminary results indicate that foliar sprays containing magnesium are more effective than soil treatments in maintaining normal leaf colour. The plant-breeding programme is concerned mainly with improvements of tomato, cucumber and lettuce.

The investigations on *Didymella* stem rot of tomato have been continued by the Plant Pathology Department, which is also concerned with powdery mildew of cucumber and wilt disease of carnation as well as mushroom diseases. Some experiments were carried out on chemotherapeutic control of tobacco mosaic virus in the tomato, but it was concluded that this approach is not promising. Although insecticides

properly applied should give adequate control of white fly, there are sometimes risks of chemical injury to plants, and for this reason interest has been revived in the method of biological control by wasp parasites. The Entomology Department has begun a series of studies on the effects of environmental factors on the fecundity and development of white fly and on the host/parasite balance. Other investigations by this Department include mushroom pests and the red spider mite. The Crop Protection Department is concerned with the control of mildew of chrysanthemums and aphids on lettuce and with the residual toxicity of certain sprays.

E C HUMPHRIES

RADIOLOGICAL HAZARDS TO PATIENTS

AT the end of 1956, the Secretary of State for Scotland and the Minister of Health appointed a committee "to review the present practice in diagnostic radiology and the use of radiotherapy in non-malignant conditions, having regard to the report of the Committee on the Hazards to Man of Nuclear and Allied Radiations".

This committee, under the chairmanship of Lord Adrian, has now produced an interim report (Ministry of Health, Department of Health for Scotland, Radiological Hazards to Patients. Interim Report of the Committee. Pp 22. London: H.M. Stationery Office, 1959. 1s 3d net) for the one completed part of its survey, namely, the use of X-rays for mass miniature radiography. The conclusion is drawn that, when properly conducted, examinations by this method make a negligible contribution to the total radiation to which the population is daily exposed. Even on the most pessimistic assumptions, the indefinite continuation of mass miniature radiography at the present rate could add no more than 20 cases of leukaemia to the annual incidence of 2,500 cases in Great Britain; it is also possible that it would produce no additional cases at all. The gonad doses, which determine the long-range genetical damage, have been found to be even smaller than previously estimated. These very small somatic and genetical risks have to be considered in relation to the undoubtedly large benefits of mass miniature radiography to the health of the population. In 1957, these examinations led to the discovery of nearly 18,000 cases of pulmonary tuberculosis and some 63,000 other abnormalities, which included lung cancer, heart disease and pneumoconiosis. For children and pregnant women, mass miniature radiography is not recommended and should be replaced by normal radiographic procedures with strict limitation of the

field to the chest. Some general principles are also given for reducing unnecessary exposure in other forms of diagnostic radiology, in particular fluoroscopy, but the survey of this area is not yet completed.

There is one statement in the introduction (paragraph 10) which may give rise to serious misunderstandings. It is stated, correctly, that a dose of radiation which would double the present mutation-rate would cause perceptible damage to the population, and that this dose is estimated to lie between 10 and 100 r per generation. It is also correct to say that at present the dose due to medical radiology does not exceed 3 rads per generation. But it is only for the sake of convenience that genetical damage is usually estimated in terms of the 'doubling dose'. There is no lower threshold to the genetical effects of ionizing radiation, and serious genetical damage will be produced already by doses which are far below the doubling dose. In fact, the report of the Medical Research Council came to the conclusion that, from the point of view of genetical hazards, "the upper limit, which future knowledge may set to the total dose of extra radiation which may be received by the population as a whole, is not likely to be more than twice the dose which is already received from the natural background, the recommended figure may indeed be appreciably lower than this". On this evidence, the danger limit has already been reached or even exceeded in countries where X-rays are used extensively for medical purposes. Against this damage to future generations we must, however, set the benefit to the present one and, although all means must be used to cut down avoidable exposure to radiation, a high amount of exposure will remain unavoidable if the present standards of medical service are to be maintained.

FEEDING THE HUNGRY

THE practical way to wage war on want was the theme of an outstanding address at St John's College, Annapolis, Maryland, on April 9 by Mr Gerard Piel, publisher of *The Scientific American*. Following an account of the way in which science has given man unlimited power and opportunities to change the material conditions of life, Piel shows how it is now possible to bring the elimination of want within the reach not only of the present

generation but also of all future generations. Want is no longer a challenge to technology, but to economics and politics; it is a social problem. Thanks principally to the control of mortality, the underprivileged peoples are living longer and feeling well enough to do something about their plight. These aroused people are still extracting the irreplaceable resources of their lands to feed the voracious appetite for raw materials of Western peoples. At present the

United States imports from overseas iron ore, bauxite, oil and a host of commodities in greater volume than ever before. In some American sections the technology is perilously dependent upon riches supplied so cheaply. The goodwill and complacency of the natives have immediate relevance to the American price structure.

It is impossible to stop at the churlish counsel that the Colonials should reduce their numbers. Their population is rising because the medium of sanitation introduced to protect white Colonials in their midst has reduced their rate of mortality as well. Their numbers are increasing, according to United Nations studies, at a rate that exceeds 1 per cent per annum. Since the end of the Second World War their material condition has been in corresponding decline, their calorie intake has actually fallen.

To offset the claim of population growth and reverse the decline in their condition, they must increase their production not at a rate greater than their population growth. To negate the differential, the faster will their lot improve. Such an objective is not only technologically but also politically and economically feasible. American industrial growth has averaged 5 per cent over long periods: it has reached 8 per cent under intense pressure. The growth of agricultural output has correspondingly proceeded at the rate of 2 per cent in normal times. In response to the economic cycle and to controlled prices and other regulatory devices, it fluctuates over an even wider range. The present curtailment of grain production in the United States represents 200 000 tons, which approximates to the calorie deficit for the underfed portion of the world population.

About 500 billion dollars over the next fifty years would secure an average gain per annum of 2 per cent in industrial production and a corresponding increase in agricultural output in non-Western areas. Not all the 500 billion dollars would have to be supplied from outside. At about the halfway point the new industrial centres would begin to generate some additional capacity of their own.

Bed rock investments, however, are not particularly attractive to the world's capital market. These

involve such elementary public utilities as communication systems, including highways as well as railroads, and dams for flood control and irrigation. Investments in such projects call for the kind of funds now written off on armaments. A long range view should be taken in looking for return on investment.

Western technology is specially qualified to contribute to the soaring demand for electrical energy which will attend industrialization programmes. But the demand for huge volumes of energy, heavy equipment and big investment would not come at the outset. First, there is need for planning and, then, engineering. Many of the early gains in these areas would be achieved with very little expenditure on capital goods. The first requirement is for brains and knowledge.

An example of what can be accomplished is furnished by Mexico. For the past twenty years the Rockefeller Foundation has been working with the Ministry of Agriculture and Animal Husbandry of Mexico. At a cost of less than 2 million dollars a year, American agronomists have been supplied to Mexico, and young Mexicans have been trained in the agricultural sciences. In this period, the food production of the country has risen 80 per cent. The gains have been achieved by improved yields of Mexico's own staple crops, the development of new varieties of wheat and potatoes and the establishment of something like the American county agent system for farmer education. Not a single tractor or fertilizer plant is in the expense account: the money has been spent on the intangibles of information, education and expert consultation. The 4 per cent per annum gain safely exceeds the 3 per cent increase in population and has brought an improvement in the people's diet which is already showing up in vital statistics.

Somewhere in American material and intellectual resources the capacity to expand on this precedent could be found. If a beginning could be made it would soon be possible to have additional wealth and brains available for the task as a result of the attenuation of the arms race on which prosperity now rests so heavily and insecurely.

SYMPATHETIC POSTGANGLIONIC MECHANISM

By PROF J H BURN, FRS, and M J RAND

Department of Pharmacology University of Oxford

DURING recent years it has been demonstrated that acetylcholine exerts an action in various organs similar to that of sympathetic stimulation. Since this action is seen in the presence of atropine and is also exerted by nicotine it follows that the action is not a muscarinic but is a nicotinic action. An example of this action is the contraction of the arrectores pili muscles in the skin of the cat's tail. This was first described by Brückner¹ for acetylcholine, and a few years later by Coon and Rothman² for nicotine. Most of the hair was removed from the cat's tail except for a few tufts, and acetylcholine or nicotine was injected into the skin at the base of the tufts. Pilo erection was then observed. Normally the pilomotor muscles are caused to contract by sympathetic stimulation, and they also contract

after the intravenous injection of adrenalin or nor-adrenalin. Other examples of sympathomimetic effects caused by acetylcholine or by nicotine in the presence of atropine are the relaxation of the isolated intestine of the kitten by nicotine³, the acceleration of the isolated atria of the rabbit⁴ and the constriction of the vessels of the perfused rabbit ear by acetylcholine and by nicotine⁵, the contraction of the isolated nictitating membrane of the cat by nicotine⁶, do Burgh Doly and Scott (unpublished work) have observed that acetylcholine injected into the splenic artery during perfusion of the spleen with blood caused contraction of the spleen. We are grateful to them for allowing us to quote this result.

These nicotine-like effects of acetylcholine, exerted at sites peripheral to sympathetic ganglia thus

the effects of sympathetic stimulation, are not seen in preparations from animals with reserpine. Tissues innervated by sympathetic nerves were found by Schmitterlów⁷, Euler and Purkhold⁸ to contain noradrenaline or with a much smaller amount of adrenaline. Treatment of rabbits with reserpine, the noradrenaline which can be extracted from the heart ears⁹. Similarly after treatment with reserpine, noradrenaline disappears from the aorta of the ear of the rabbit, from the skin of the rabbit's ear and from the skin of the cat's tail, from the cat's ear and from the iris of the cat's eye¹⁰.

The nicotine-like actions of acetylcholine are also seen when the sympathetic fibres degenerate, and this degeneration is also accompanied by a loss of the noradrenaline which can be extracted from the nerves^{8,10b}.

The conclusion may therefore be drawn that the nicotine-like actions of acetylcholine which have been described are due to the release of noradrenaline (possibly with adrenaline also) from the sympathetic nerves.

At present we are uncertain of the location of the noradrenaline in the organ. Euler¹¹ believes that it is contained within the postganglionic fibres, calculating that the amount may be 3-30 mgm/gm. This is one thousand times more than that in postganglionic fibres before they reach the organ. This amount is only of the order of 15 µgm/gm. The disappearance of the noradrenaline after degeneration of the nerves is readily explained if it is present in the nerves.

There is some evidence, which as yet is only suggestive, that the noradrenaline and adrenaline in the organs might be present in cells containing chromaffin granules. Such cells have been described in human skin by Adams-Ray and Nordenstam¹², and also by Burch and Phillips¹³. They have been found in the skin of the rabbit's ear, in the skin of the cat's tail and in the nictitating membrane. The chromaffin granules are greatly reduced or disappear in the tissues of animals treated with reserpine, or in tissues in which the sympathetic fibres have degenerated^{10a,c}. Thus it is possible that the nicotine-like actions of acetylcholine are due to the release of noradrenaline and adrenaline from cells containing chromaffin granules. However, Muscholl and Vogt¹⁴ have found that reserpine depletes the noradrenaline stores in the sympathetic neurones more readily than those in chromaffin cells.

Tyramine is a sympathomimetic amine which ceases to act after degeneration of the sympathetic fibres¹⁵. Its pressor action is also absent in the cat previously treated with reserpine¹⁶. The conclusion may be drawn that tyramine exerts its action by liberating noradrenaline and adrenaline from the store in the organ. Since an infusion of noradrenaline into the vein of a cat or into the blood perfusing the hind-leg of a dog increases the pressor and constrictor action of tyramine, or restores it when it is absent due to previous treatment with reserpine, it appears that the store of noradrenaline in the organ can be increased by taking up noradrenaline from the blood stream¹⁷.

The effect of sympathetic stimulation also is increased as a result of an infusion of noradrenaline. If the volume of one hind-leg of a dog is recorded in experiments in which the lumbar sympathetic chain is stimulated, then, atropine having been given, the threshold strength of stimulus for causing vaso-

constriction in the hind-leg can be determined. Following an infusion of noradrenaline, the total amount given to the dog being 0.2-1.0 mgm in the course of 20 min., the threshold has been observed to fall to a mean of 40 per cent of its previous value. In experiments in which the dog's hind-leg has been perfused it has been observed that the effect of a given sympathetic stimulus was greatly increased. These observations indicate that the efficiency of sympathetic stimulation depends on the amount of noradrenaline in the neighbourhood of the nerve endings. This may be taken up from the blood into the nerve endings themselves or into chromaffin cells, one of the functions of the noradrenaline secreted by the adrenal medulla may be to fill up this store.

We have now considered evidence that the nicotine-like actions of acetylcholine are due to the release of noradrenaline from a store near the sympathetic nerve endings, we have seen that this store can take up noradrenaline which is circulating in the blood, and we have seen that the effect of sympathetic stimulation depends on the size of this store. We now turn to the sympathetic impulses themselves.

When a cat is treated with reserpine with the result that the stores of noradrenaline and of adrenaline are depleted, the effect of tyramine on the nictitating membrane is completely absent, but stimulation of the postganglionic sympathetic fibres still causes a contraction. The threshold strength for this effect is greater than the threshold in the normal cat. We have found that the contraction produced is augmented by eserine and is abolished by atropine, and the contraction must therefore be due to the release of acetylcholine from the sympathetic fibres. The presence of cholinergic fibres in the sympathetic supply to the nictitating membrane was suggested by Bacq and Fredericq¹⁸. Recent work shows that the presence of cholinergic fibres is still more widespread. Thus Gillespie and Mackenna¹⁹ have found that when a rabbit is treated with reserpine, the isolated colon is caused to contract by sympathetic stimulation instead of to relax, and that the contraction is abolished by atropine. They concluded that cholinergic fibres are present in the sympathetic supply.

Huković²⁰, working in this Department, has made an isolated preparation of rabbit atria with the sympathetic nerves attached, when the sympathetic fibres from the stellate ganglion were stimulated the rate and amplitude of the atrial beat increased. If the rabbit was treated beforehand with reserpine some preparations responded to sympathetic stimulation by inhibition, the inhibitor effect being increased by eserine and abolished by atropine. This result suggests that cholinergic fibres are present in the sympathetic supply from the stellate ganglion to the atria.

Observations have also been made on the cat spleen, recording the changes in volume of the spleen by a plethysmograph. The nerves were separated from the splenic artery near the beginning of the artery. Stimulation caused contraction of the spleen which was unaffected by atropine. When the cat was treated beforehand with reserpine, it was found that in some preparations acetylcholine caused a dilatation of the spleen, and that stimulation of the nerves was also followed by dilatation. This dilatation was increased in the presence of eserine and abolished by atropine. Thus the splenic nerves also contain cholinergic fibres. Observations have also been made on the

virgin cat uterus, recording its contractions *in situ* under chloralose anaesthesia. When the hypogastric nerves were stimulated, inhibition followed. When the cat was treated beforehand with reserpine, stimulation of the hypogastric nerves caused a small contraction which was greater in the presence of eserine and which was abolished by atropine. The evidence suggests that the hypogastric nerves contain cholinergic fibres.

The observations that the nicotine-like effects of acetylcholine resemble those of sympathetic stimulation, and that these effects are exerted by the release of noradrenaline (or adrenaline) must now be put aside by side with the evidence of the existence of cholinergic fibres in postganglionic sympathetic fibres in various places where they were not suspected. It then appears that such cholinergic fibres may be adrenergic in their effect, because the acetylcholine which they liberate will cause the discharge of noradrenaline or of adrenaline from the peripheral store. The stimulation of such fibres can in theory have two effects, one, normally much the smaller, due to the direct action of the acetylcholine released, an action which is sensitive to atropine, and the other, normally much the greater, due to the released acetylcholine causing a discharge of noradrenaline from the store, a nicotine-like action not affected by atropine. This double effect may actually be present in the nictitating membrane where the response to postganglionic stimulation in the normal cat is slightly diminished by atropine, for example to about 80 per cent of its initial size.

Such a double effect might explain the response to stimulation of the sympathetic supply to the muscles of the dog's hind leg, where Burn¹⁴ observed that a stimulus for 3 sec caused dilatation, while the same stimulus applied for 30 sec caused in the main constriction. A double effect is possible only when acetylcholine has a direct muscarinic action of its own. Thus in the cat treated with reserpine, stimulation of the sympathetic fibres has no pilomotor effect

in the tail. The accumulated evidence thus requires consideration of a new possibility. The adrenergic sympathetic fibre has been thought of as liberating noradrenaline in the same way as cholinergic fibres liberate acetylcholine. However, cholinergic fibres, which seem widespread in the postganglionic sympathetic supply, may liberate noradrenaline from the store at the nerve endings and thus be adrenergic in effect.

In this account we have kept open the possibility that noradrenaline may not always be the main component of the peripheral store and that around some sympathetic nerve endings in the virgin cat uterus for example adrenaline may be more important. We have no evidence on this as yet. We may also recall that Pines¹⁵ has described the chromaffin cells in sympathetic ganglia and has given a detailed account of his findings that they are innervated.

PROTEIN BIOSYNTHESIS AND OXIDATIVE PHOSPHORYLATION IN ISOLATED RAT LIVER MITOCHONDRIA

By P. J. REIS, J. L. COOTE and T. S. WORK

National Institute for Medical Research, Mill Hill, London NW7

ELECTRON microscopy combined with differential centrifugation of sucrose homogenates has shown that liver parenchymal cells have a complex cytoplasmic structure¹. After intravenous injection of amino acids labelled with carbon 14 the proteins of the subcellular cytoplasmic structures of these cells become labelled at different rates. In both rats and guinea pigs the liver microsomal fraction is labelled considerably more rapidly than the mitochondrial material. Labelling is particularly rapid in the ribonucleoprotein fraction of the microsomes². The suggestion has been made that protein synthesis takes place mainly in the microsomal ribonucleoprotein fraction and that mitochondria acquire radioactive protein from the microsomal fraction. The present results and those of Bates *et al.*³ indicate that rat liver mitochondria are capable of independent protein synthesis.

Mitochondria were isolated from rat liver by differential centrifugation of a 1:4 sucrose homogenate. Best results were obtained with a mixture containing sucrose (0.3 M), versene (0.002 M) and nicotinamide (0.03 M); this mixture will be referred to as SVN. The fraction collected between 1.000 and 0.0007 was washed by four successive cycles of re-suspension and precipitation from SVN. Washed mitochondria in a mixture of sucrose (0.16 M), phosphatidyl (0.01 M), tris buffer (0.02 M), MgSO₄ (0.008 M) and sufficient KCl to maintain tonicity showed negligible incorporation of labelled amino acids into mitochondrial protein during aerobic incubations. The mitochondrial protein was obtained by precipitation with trichloroacetic acid and treatment to remove adsorbed amino acids, ribonucleic acid and lipids. Incorporation was stimulated by the addition of either succinate or α -ketoglutarate.

Ordinates left, per cent of initial rate of oxidative phosphorylation, right, counts per min.

Fig 1 Dependence of incorporation of amino-acid into mitochondrial protein upon oxidative phosphorylation. Washed mitochondria from about 3 gm rat liver were suspended in 5.5 ml of medium of the following composition: *tris* buffer (0.05 M), potassium phosphate (0.01 M), potassium succinate (0.01 M), magnesium sulphate (0.008 M), potassium chloride (0.065 M), versene (0.0013 M), nicotinamide (0.02 M), ^{14}C -*Chlorella* protein hydrolysate (5 μC), sucrose (0.11 M), added as 2.0 ml boiled cell sap. Incubations were at 30°, in an atmosphere of oxygen. Oxidative phosphorylation was measured essentially as described by Slater (ref 10), glucose-6-phosphate was estimated by the method of Kornberg and Horecker (ref 11).

together with cell sap. At an early stage in the investigation it was found that, contrary to the report of Greengard⁴, boiled cell sap was just as effective as whole cell sap. Both the rate and the duration of amino-acid incorporation into mitochondrial protein could be increased by adding progressively larger quantities of boiled cell sap. The incorporation reaction was stimulated by incubation in oxygen instead of air and almost completely inhibited by incubation in nitrogen or by the addition of dinitrophenol or cyanide. The behaviour of the incorporation reaction towards inhibitors indicated that incorporation was probably linked to oxidative phosphorylation, amino-acid incorporation and oxidative phosphorylation were accordingly measured in the same mitochondrial preparation. The results (Fig 1) showed that as the rate of oxidative phosphorylation declined, the rate of incorporation declined in a similar manner.

The duration of oxidative phosphorylation in isolated rat liver mitochondria is notoriously sensitive to conditions of incubation⁵. Calculation of the amount of adenine nucleotide in boiled cell sap indicated that the final concentration of nucleotides in the incubation mixture was below that usually required to maintain mitochondrial structure and oxidative phosphorylation. Accordingly, the boiled cell sap was supplemented with 0.004 M adenosine monophosphate and 0.0005 M diphosphopyridine nucleotide. Mitochondria incubated under these conditions were able to maintain oxidative phosphorylation and incorporation of labelled amino-acids for 2 hr at 30°, although the rate of incorporation was falling off after 1 hr. The work of Siekevitz and Potter⁵ and of Pressman⁶ indicates that the balance of nucleotides and of inorganic phosphate

inside the mitochondrial membrane is best maintained when an acceptor for energy-rich phosphate bonds is present in the medium. Thus when the system was further supplemented with hexokinase and glucose, incorporation of amino-acids into mitochondrial protein could be maintained at, or near, a linear rate for 2 hr at 30°. Incubations have not been carried beyond 2 hr.

Mitochondria are composed of a structurally complex double membrane within which are disposed various soluble but rather firmly bound enzymes. It was found that in the presence of adenosine monophosphate and diphosphopyridine nucleotide, both with and without hexokinase, the insoluble proteins of the mitochondria were effectively labelled either by a mixture of amino-acids labelled with carbon-14 or by a single labelled amino-acid (phenylalanine). Soluble protein was not, however, significantly labelled even after 2 hr at 30° (soluble protein was released either by the butanol method of Morton⁷ or by the extraction of an acetone-dried powder of mitochondria with phosphate buffer). Increase in the amount of boiled cell sap, with maintenance of the adenosine monophosphate and diphosphopyridine nucleotide concentration at the level given above, resulted in a substantial improvement in the efficiency of labelling of the insoluble protein and produced slight activity in the soluble protein. Boiled cell sap contains substantial quantities of amino-acids (80 μgm amino-nitrogen/ml) and it was found that these could be replaced by a complete mixture of 20 amino-acids. It was found that, as the concentration of these amino-acids in the incubation medium was progressively increased, the incorporation into insoluble protein rose to a maximum at an amino-acid concentration of 30–40 $\mu\text{M}/\text{ml}$. The incorporation into soluble protein was initially low, but as amino-acid concentration was increased, the radioactivity of the soluble protein continued to rise in an approximately linear manner. Thus the incorporation into soluble protein of the mitochondria progressively becomes a greater proportion of the total incorporation, as amino-acid concentration is increased. The most likely explanation of these results is that there are relatively few sites of protein synthesis in mitochondria (templates?). When these sites become saturated with incoming radioactive amino-acid further increase in amino-acid concentration (of fixed specific radioactivity) will not result in any further increase in radioactivity of insoluble protein. Increased amino-acid concentration will result, however, in a progressively greater tendency for newly synthesized protein to be displaced from the sites of synthesis into the intracisternal spaces so that there will continue to be a progressive increase in the rate of accumulation of radioactivity in soluble protein.

There is no doubt that the amino-acid incorporation reaction measured in these experiments is truly intramitochondrial and is not due to adherent microsomes. First, incorporation is not abolished by thorough washing of the mitochondria as described previously (this washing procedure has been shown to remove at least 95 per cent of microsomes labelled with carbon-14 added to the sedimented mitochondria), secondly, the incorporation reaction does not require fresh cell sap with its supply of soluble ribonucleic acid⁸ and 'amino-acid activating' enzymes, thirdly, the incorporation is much more prolonged than that obtained with microsomes *in vitro*, and fourthly, the incorporation is quite unaffected by addition of ribonuclease to

the incubation mixture. This does not, however, prove that ribonucleic acid plays no part in amino acid incorporation since we have found that, even after 2 hr at 30° in the presence of ribonuclease, mitochondria retain about 70 per cent of their ribonucleic acid (originally 17 µgm/mgm mitochondrial protein). Indeed, the incorporation reaction in mitochondria may have closely similar characteristics to that occurring in microsomes since we have found that an extract of mitochondria will catalyse an amino acid-dependent exchange between adenosine triphosphate and radioactive pyrophosphate (Table 1).

Table 1 AMINO-ACID ACTIVATION IN RAT LIVER MITOCHONDRIA

| Extract of mitochondria prepared from | c.p.m. per µmole adenosine triphosphate | | |
|--|---|---------------------|------------------------------------|
| | No amino-acids | Plus amino-acids | Increment due to amino-acids |
| 0.6 gm. Liver | 1,810 | 2,400 | 580 |
| 1.2 gm. Liver | 3,060 | 4,280 | 1,220 |

Mitochondria were isolated and washed four times in an acetone powder was prepared and extracted with 0.1 M tria buffer pH 7.6. This soluble extract was incubated with tria buffer pH 7.6, 100 µmoles magnesium chloride, 2 µmoles adenosine triphosphate, 5 µmoles a mixture of 12 amino-acids, 2 µmoles of each ³²P pyrophosphate about 2 µmoles 160,000 c.p.m. vol 1 ml incubated for 16 min 37°.

Before one can be convinced that the amino acid incorporation observed in these experiments represents true synthesis of protein, it would be necessary to demonstrate synthesis of a specific protein. In this regard the synthesis of cytochrome c has already been demonstrated in isolated mitochondria from rat liver² and calf heart³. The presence of numerous enzymes within mitochondria suggests that this *in vitro* system should be a valuable tool in further studies on protein biosynthesis. Work has already been initiated along these lines.

STRUCTURE OF A MELANOCYTE-STIMULATING HORMONE FROM THE HUMAN PITUITARY GLAND

By Dr. J. I. EUAN HARRIS*

Department of Biochemistry University of Cambridge and the Biological Laboratories Harvard University

A MELANOCYTE-STIMULATING substance from human pituitary glands has recently been isolated in pure form by ion-exchange chromatography.¹ It has been shown to be a slightly basic polypeptide which migrates as a single substance when submitted to ionophoresis on paper in pyridine acetic acid buffers at pHs of 3.6 and 6.5.

The amino acid sequence of the polypeptide hormone has been investigated by methods similar to those described^{2,3} for the elucidation of the structure of a melanocyte-stimulating hormone from pig pituitary glands. The particular methods which have been used were to a great extent determined by the limited amount of the substance (4-6 mgm.) which was available for study.

Specific colour tests⁴ carried out on the intact polypeptide showed that it contained tryptophan, tyrosine, histidine and arginine; and when a total acid hydrolysate was submitted to qualitative chromatographic analysis on paper the following amino acids were shown to be present: alanine, arginine, aspartic acid, glutamic acid, glycine, histidine, lysine, methionine, phenylalanine, proline, serine and tyrosine.

A sample of the hormone (2.5 mgm.) was allowed to react with chymotrypsin (0.1 mgm.) in 0.05 M ammonium bicarbonate (2 ml.) at pH 8.0-8.5 and 37° for 10 hr. When the product was fractionated by ionophoresis on paper in pyridine acetic acid (pH 6.5) at 40 volts/cm for 2 hr it was resolved into five peptide fragments.

* Member of the Scientific Staff of the Medical Research Council (at present Research Fellow in Biology Harvard University Cambridge Mass.)

Table 1 AMINO ACID COMPOSITION AND C-TERMINAL AMINO-ACIDS OF PEPTIDES PRODUCED BY CHYMOTRYPSIN HYDROLYSIS OF HUMAN β -MELANOCYTE-STIMULATING HORMONE

| Peptide | Amino-acid composition | C-terminal group |
|----------------|-----------------------------------|------------------|
| C ₁ | Ala, Asp, Glu, Gly, Lys, Pro, Tyr | Tyr |
| C ₂ | Arg, Asp, Gly, Lys, Pro, Ser, Tyr | Asp |
| C ₃ | Arg, Glu, His, Met, Ile | Phe |
| C ₄ | Asp, Gly, Lys, Ile, Ser | Asp |
| C ₅ | Arg, Tyr | Tyr |

The amino acid compositions of these five peptides (C₁, C₂, C₃, C₄, and C₅) were determined by means of specific colour tests⁴, and by paper chromatographic analysis of their total acid hydrolysates, the corresponding C-terminal amino-acids were determined by means of carboxypeptidase⁵. The results, summarized in Table 1, showed that the human melanocyte stimulating hormone was of the β melanocyte stimulating hormone type, and that it was closely related in terms of chemical structure to β melanocyte-stimulating hormone⁶ from pig pituitary glands. Thus, peptides C₁, C₂, C₃, and C₄ were found to have the same electrophoretic mobilities at pH 3.5 and pH 6.5, and the same qualitative amino acid compositions (with the exception of C₃, which contained arginine instead of lysine), as the corresponding peptide fragments⁶ derived from pig β -melanocyte stimulating hormone by digestion with chymotrypsin. Peptide C₅ on the other hand differed from the corresponding peptide fragment from pig β -melanocyte-stimulating hormone both in electrophoretic and chromatographic behaviour, and in amino-acid composition, although the C-terminal amino-acid,⁷

tyrosine, and four of the other constituent amino-acids—aspartic acid, glutamic acid, glycine and proline—were common to both peptide fragments

The presence of lysine suggested that C_1 would be susceptible to the action of trypsin. It was therefore allowed to react with trypsin for 4 hr at 37°, when the product of reaction was fractionated by ionophoresis at pH 6.5 it was resolved into two major (C_1TA_1 , C_1TB_1) and two minor (C_1TA_2 , C_1TB_2) components. Their qualitative amino-acid compositions were determined and are given in Table 2.

Table 2. AMINO-ACID COMPOSITION AND C-TERMINAL AMINO-ACIDS OF PEPTIDES PRODUCED BY TRYPTIC HYDROLYSIS OF PEPTIDE C_1 (Table 1)

| Peptide | Amino-acid composition | C-terminal group |
|-----------|------------------------------|------------------|
| C_1TA_1 | Asp, Glu, Gly, Lys, Pro, Tyr | Tyr |
| C_1TB_1 | Ala, Glu, Lys | Lys |
| C_1TA_2 | Asp, Glu, Gly, Pro, Tyr | Tyr |
| C_1TB_2 | Lys | — |

One of the minor peptide components, C_1TA_2 , appeared to be identical with the N-terminal peptide, Asp Glu Gly Pro Tyr, in pig β -melanocyte-stimulating hormone⁶, as judged by its electrophoretic mobility at pH 6.5, R_F in butanol-acetic acid-water (4:1:5), amino-acid composition, and C-terminal group. The two major peptide components, C_1TA_1 and C_1TB_1 , were both found to contain lysine, and the fact that a significant amount of free lysine (C_1TB_2) was also formed in the tryptic reaction suggested that the parent molecule, C_1 , contained a Lys-Lys bond, and that it was the N-terminal peptide (Ala, Glu) Lys Lys (Asp Glu Gly Pro) Tyr in the human β -melanocyte-stimulating hormone molecule.

After their homogeneity had been established both by electrophoretic and chromatographic analysis, peptides TA_1 , TA_2 , TB_1 and C_2 were submitted to partial acid hydrolysis (12 N hydrochloric acid, for 3–6 days at 37°), peptide C_3 was hydrolysed with subtilisin⁸ (12 hr at 37°). The respective products of reaction were fractionated by ionophoresis on paper and were characterized by the procedures which have been described previously^{3,6}. The results are summarized in Table 3.

Peptide C_2 was shown to give additional amounts of C_5 and C_6 when it was redigested with chymotrypsin, showing that C_5 and C_6 formed contiguous sequences in the molecule. By means of carboxypeptidase, C_6 was shown to be a dipeptide containing arginine and tryptophan, in a similar manner aspartic acid was shown to be the C-terminal amino-acid in both C_2 and C_3 , showing that these two peptides formed the C-terminal sequence, Arg Try (Gly, Ser, Pro, Lys). Asp, in human β -melanocyte-stimulating hormone (cf ref 6).

Although it was not possible to undertake quantitative amino-acid and end-group analyses on the parent molecule, the results which have been

Table 3. PEPTIDES IDENTIFIED IN PARTIAL ACID* (12 N HYDROCHLORIC ACID, 37°) AND SUBTILISIN† HYDROLYSATES

| Peptide | Products of partial hydrolysis |
|-------------|--|
| * C_1TB_1 | Ala Glu, Glu Lys |
| * C_1TA_1 | Lys Asp, Lys Asp Glu, Glu Gly, Gly Pro Tyr |
| * C_1 | Ser Pro, Ser Pro Pro, Ser Pro Pro Lys, Pro Pro Lys, Pro Lys, Lys Asp |
| † C_2 | Arg Met, Arg Met Glu, Glu His, Glu His Phe |

obtained with peptide fragments derived from it by hydrolysis with chymotrypsin and trypsin nevertheless appear to be sufficient to establish that human β -melanocyte-stimulating hormone contains twenty-two amino-acid residues, and that they occur in the following sequence

1 2 3 4 5 6 7 8 9 10 11
H—Ala Glu Lys Lys Asp Glu Gly Pro Tyr Arg Met
12 13 14 15 16 17 18 19 20 21 22
Glu His Phe Arg Try Gly Ser Pro Pro Lys Asp —OH

This appears to be the first of the polypeptide hormones from the human pituitary to be isolated in pure form and to be characterized in terms of its complete chemical structure. The amino-acid sequences of human, pig^{6,7} and ox⁸ β -melanocyte-stimulating hormones and pig α -melanocyte-stimulating hormone^{2,3} are compared in Fig 1.

Although human β -melanocyte-stimulating hormone manifests a structural 'species' difference of the 'classical' type, namely, the replacement of a lysine residue (position 6 in pig and ox β -melanocyte-stimulating hormone) by arginine (position 10 in human β -melanocyte-stimulating hormone) in structurally related positions, the presence of the additional N-terminal tetrapeptide, Ala Glu Lys Lys, represents a hitherto unprecedented structural species variation among naturally occurring biologically active polypeptide and protein molecules of relatively low molecular weight (for example, vasopressins^{10,11}, corticotropins¹², insulins¹³ and hypertensins^{14,15}).

Ox β -melanocyte-stimulating hormone⁸ is found to differ from pig β -melanocyte-stimulating hormone only in position 2 (Fig 1), where the glutamic acid residue in the pig hormone is replaced by a serine residue in the ox hormone. It is perhaps significant that the replacement of one amino-acid by another which is structurally unrelated to it occurs in a part of the molecule which does not appear to be specifically essential for its biological activity³ (cf corticotropins¹²). Presumably genetical alterations which produce structural modifications of this type in essential parts of the molecule would result in the formation of molecules in which biological specificity was either modified or destroyed. Consequently the fact that a lysine residue in the pig and ox hormones is replaced by the structurally related amino-acid, arginine, in the human hormone, and that the structural features common to all known β -melanocyte-stimulating hormones and corticotropins^{12,16}

Fig 1. Amino-acid sequences of melanocyte stimulating hormones from pig, ox and human pituitary glands. MSH, melanocyte-stimulating hormone.

remain intact, suggests that the amino acids which occupy these key positions in β melanocyte-stimulating hormone are directly associated with its biological activity in the *in vivo* environment in which it has been designed to function as a hormone.

In a melanocyte stimulating hormone, on the other hand, there is an interchange of lysine and serine residues between positions 3 and 11 (Fig 1), which correspond to positions 6 and 14 in pig and ox β melanocyte stimulating hormones and to positions 10 and 18 in human β melanocyte stimulating hormone. This would suggest that factors other than the linear arrangement of amino acid residues must be taken into consideration in relating structure to biological function in the living cell even in comparatively small peptide molecules which do not appear to possess any ordered secondary or tertiary structure in aqueous solution.

I am indebted to Dr H. B. F. Dixon for his generous gift of the sample of pure human melanocyte-stimulating hormone. Most of the experimental work was carried out in the Division of Biochemistry of the Massachusetts Institute of Technology, and I am indebted to Dr Vernon Ingram for his kindness in placing the facilities of his laboratory at my disposal. GROWTH PATTERNS IN NEUROSPORA

A Biological Clock in Neurospora

MANY fungi produce alternating zones of different growth type in response to diurnal light-cycles and temperature cycles, and in some cases the zonation will continue to be produced for a time in continuous darkness and at a constant temperature. In 1953 Brandt¹ reported observation of zonation in the growth and conidia formation of *Neurospora crassa* mycelia in standard glass race tubes maintained in constant darkness, humidity and temperature. Inspection of Brandt's photographs suggested to us that the zones were formed with a frequency of approximately one a day and we have tested the implication that there does occur in *Neurospora* a typical biological daily clock—that is, a rhythmic system with an innate circadian ('about a day') period which is relatively independent of the temperature. (We are here adopting the suggestion (personal communication) of Prof F. Halberg that the word 'circadian' obviates all the long standing confusion inherent in the words diurnal, daily, 24 hr., as adjectives to describe the rhythms with which we are concerned.)

Brandt reported that he obtained zonation in only one (No 21807, prolineless) strain of several that he examined, and that the zonation occurred on only one of the supplemented media (Grav's) that would support growth of this strain. Zonation occurred at constant temperature either in a 24 hr light-dark cycle or in continuous darkness after a brief period of initial growth in white light. Zonation does not develop if the mycelium is maintained in continuous white light; but we have found that it can develop in continuous red (carbon) light.

In the experiments reported here the same strain and media as those used by Brandt were also used. Freshly inoculated race tubes were placed in a tem-

perature-controlled cabinet containing a 14 watt cool white fluorescent lamp. About 40 hr later when the mycelium was growing well, the white light was discontinued and a red lamp was turned on. At this time and at 24 hr intervals thereafter the advance of the mycelial front was observed (in the red light) and marked on the race tube. When the growth had reached the end of the agar, the tube was removed from the growth cabinet and a densimeter device was used to measure relative density of the mycelium along its entire length. The observed phenomenon consists of alternating zones of sparse and dense mycelium. Preliminary experiments failed to reveal any significant difference in the linear growth increments in the 4 hr intervals throughout any 24 hr interval. The distribution of mycelial density has accordingly been converted from its observed spatial scale to a temporal scale. Regions of dense growth show up as maxima on the densimeter graphs.

Fig 1 illustrates the results so obtained from two typical race-tubes, one maintained at 31°C and the other at 24°C. Table 1 summarizes more extensive data on the time interval between successive maxima on the densimeter graphs. This interval, which is the period of the rhythm, is about 22 hr and is the same at the two temperatures.

The zonation of *N. crassa* thus is regulated by a rhythmic phenomenon which manifests the essential features of a biological clock.² The rhythm has an innate free running period which is close to 24 hr, relatively independent of the temperature. The rhythm can be entrained by a 24 hr light cycle. In addition to possessing these functional prerequisites of a good chronometer the rhythm also possesses other features of typical circadian systems: (1) The phase of the rhythm can be established by a single transition from light to dark; (2) as with many other plant rhythms the manifestation of the rhythm is

tube after 24 hr. However, six of the cultures had a lag period of about three days before any growth appeared. These were the six proline requiring *pat* + segregants of the first cross (Table 1). There is thus a physiological interaction which might be described as partial suppression of *pat* by *pat* (though it could also be suppression by mating type gene *a*). Whether this interaction is related to the function of the biological clock is unknown. (The lag period occurred only on Gray's medium; none of the cultures lagged on minimal medium plus proline or on complete medium.)

The tests for proline requirement were made on plates containing the sugar sorbose; this causes growth to remain restricted to the spot of the inoculum, rather than spreading over the plate. The use of sorbose medium allows as many as twenty five growth tests to be performed on a single plate. It was observed that some of the test colonies did not remain confined on the sorbose plates, but were expanding radially 5-10 mm per day. The 'sorbose escape' condition turned out to be characteristic of the patch segregants. This was a consistent correlation: all 42 *pat* progeny from the two crosses escaped on sorbose while all 42 *pat* + progeny remained confined on sorbose. There was no evidence of any cyclic pattern in the sorbose escape colonies. Sorbose-escape was achieved even on plates held in constant light, a condition in which the cyclic growth pattern is not observed on Gray's medium.

The sorbose-escape classification demonstrates that the presence of the patch gene can be detected in a situation in which it is not visibly related to a biological clock. It is possible that the patch gene is not directly involved in the function of the biological clock but, rather, effects a growth habit which reveals an underlying clock. However, this could only be determined conclusively by a demonstration of clock activity in a *pat* + strain.

This work was supported by a grant from the National Science Foundation. I am grateful to Dr C S Pittendrigh and Dr V G Bruce, of Princeton University, for providing the strain 21803a.

PROTHORACIC GLAND STIMULATION BY JUVENILE HORMONE EXTRACTS OF INSECTS

By DR LAWRENCE I GILBERT* and DR HOWARD A SCHNEIDERMAN

Department of Zoology Cornell University Ithaca, New York

THE juvenile hormone was first recognized as the agent which prevents maturation of young insects¹. A second role for this hormone, discovered shortly thereafter, was in egg development where,

in many insects it is necessary for oötheca deposition². The present article describes what appears to be a third role for the juvenile hormone, namely stimulation of the prothoracic glands. This trophic action has hitherto been assigned either to a hormone secreted by the insect's brain³ or occasionally to low

* Present address: Department of Biological Sciences, Northwestern University, Evanston, Illinois.

Evoked responses to flash were displayed on an oscilloscope and filmed while the cat was resting facing the stroboscope. The flash, delivered once in approximately 2 sec, was of 1-m sec duration with an intensity of approximately 1 lambert. A mouse was introduced between stroboscope and cat, separated from the latter by a transparent plastic sheet. During the first few presentations of the mouse, the cat usually was intensely excited, but later it sat still, intently watching the mouse with little or no pilo-erection, or unsheathing of the claws. At this time 20 evoked responses to flash were recorded. Ten of these experimental responses were selected at random from the 20, together with 10 control evoked responses from the resting animal, recorded immediately before introduction of the mouse. The mean of each of these sets of results was calculated. These means for each animal were tabulated and the significance of any differences between experimental and control conditions obtained by applying a paired *t* test. It was found that when the cat was watching the mouse the electrocorticograph was flattened. The surface positive component of the primary wave of the evoked potential was decreased by 27 per cent ($P < 0.001$), and its duration reduced by 20 per cent ($P < 0.01$). The amplitude of the surface negative component was decreased by 21 per cent ($P < 0.02$). The excursion of the second wave of the response was reduced by 19 per cent ($P < 0.02$) and waves of the later components by 51 per cent ($P < 0.001$).

In order to orientate the cat's behaviour to a non-visual modality, the animal was conditioned to receive a slight shock to the fore-limbs after several tones, each delivered in the interval between consecutive flashes. The number of tones delivered prior to the shock was varied between 2 and 10 in any trial. After the first few trials, shocks were only occasionally applied. During the early stages of conditioning, at the onset of the tones, the cat looked intently around the box. At this time the electrocorticograph was reduced in amplitude. The surface positive component of the primary wave was reduced by 21 per cent ($P < 0.02$) and its duration by 19 per cent ($P < 0.02$). The amplitude of the second wave of the response was attenuated by 34 per cent ($P < 0.01$) and the later oscillations by 40 per cent ($P < 0.02$).

At a later stage of conditioning, the cat did not look around the box during the tones, but remained still except for some slight shifting of the fore-limbs,

twitching of the facial muscles and flicking of the ears. Occasionally at this stage the cat got up during the tones and settled in another part of the cage. Measurement of records taken when the animal showed minimal movement and when its response to the acoustic stimulus was accompanied by little or no visual searching component showed that the amplitude of the electrocorticograph was diminished. The amplitude and duration of the evoked responses were not, however, significantly different from those recorded under control conditions.

From the above results it appears that photically evoked responses in the visual cortex are not attenuated when a cat's behaviour is orientated to an acoustic stimulus, so long as there is no visual searching component in the animal's behavioural response. On the other hand, when the animal's behaviour is directed to a stimulus in the visual field, or shows some visual searching component in its response to a non-visual stimulus, evoked potentials are reduced in amplitude. It might be argued that when the cat was looking at a mouse the information contained in the flash was irrelevant and so attenuated. However, when the animal's behaviour was directed to the acoustic stimulus, in the absence of visual searching activity, the information from the flash was likewise irrelevant. The evoked potentials in these two situations should therefore have been treated similarly. They were not.

Reduction in amplitude of an evoked response to a given photic input may be brought about in one or more ways (for example, inhibition, reduction of facilitation, occlusion). Whatever the mechanism, one of the effects of such activity may be, in some circumstances, to increase sensory contrast and so improve the sharpness of input boundaries. Absence of such input attenuating activity in the visual system, as when behaviour is directed to an acoustic stimulus, could give a greater absolute sensitivity in the visual pathway. The animal would thus monitor its environment more sensitively so providing central mechanisms with a maximum of information on which to act.

INFLUENCE OF UNBALANCED GROWTH ON SUBSEQUENT X-RAY-INDUCED INHIBITION OF DEOXYRIBONUCLEIC ACID SYNTHESIS IN *ESCHERICHIA COLI* 15_T

By DANIEL BILLEN

Department of Biology, Section of Microbiology, University of Texas, M. D. Anderson Hospital and Tumor Institute, Houston, Texas

IN an earlier report¹ it was demonstrated that the number of survivors among X-irradiated *Escherichia coli* strains B/r and 15_T (thymine-less) was increased when log-phase cells were incubated in the presence of chloramphenicol prior to X-ray exposure. In the case of *E. coli* 15_T deoxyribonucleic acid synthesis was necessary for the development of radioresistant cells, since when deoxyribonucleic

acid synthesis was prevented by the removal of thymine from the pre-irradiation incubation medium, radioresistance was not enhanced by chloramphenicol. One interpretation of these results was that 'surplus' deoxyribonucleic acid formed in the presence of chloramphenicol (higher ratio of deoxyribonucleic acid/protein than in non-treated cells) was biologically active and increased the number of sensitive sites

in the bacterium¹. An additional possibility considered was that pretreated cells, unbalanced in macromolecular constituents, were in special physiological states such that the probability of overcoming X ray induced lesions was increased. Using cells in the several unbalanced states with regard to protein, deoxyribonucleic acid, and ribonucleic acid levels we have studied deoxyribonucleic acid synthesis after X ray exposure of such cells. In the present work results are presented which show (1) An inhibition by chloramphenicol of phasing or 'synchronization' of the deoxyribonucleic acid synthesizing system and (2) that the radiosensitivity of the synthesizing mechanism is altered by previous chloramphenicol exposure.

The conditions for obtaining log phase as well as establishing 'unbalanced phase' growth were those previously described¹. Following the various treatments to be described for obtaining unbalanced growth the cells were cooled in an ice bath, harvested, washed and resuspended in cold minimal salts-glucose medium to give a final concentration of about 20 times the original number ($1-2 \times 10^{10}$ cells/ml) in order to obtain satisfactory levels of material for chemical analysis. The concentration of cells during exposure was higher than the level used in the earlier studies by a factor of approximately 100, as a result the number of colony formers found after a dose of 10,000 r was higher in the experiments reported here²². Following X ray exposure at ice bath temperature the cells were added to twice the original culture volume of pre-warmed minimal medium supplemented with 20 μ g./ml. thymine and re incubated with aeration at 37° C. Aliquots of this culture were removed at intervals for analysis as detailed earlier¹.

Prior to treatment with 10,000 r of X rays, log phase *E. coli* 15r- cells were incubated in minimal medium at 37° C for 1 hr under the following conditions: (A) incubation in the presence of thymine (normal log phase cells), (B) incubation in the presence of 10 μ g./ml. chloramphenicol and (1) plus thymine (increased ribonucleic acid and deoxyribonucleic acid/protein content), or (2) without thymine (increased ribonucleic acid/deoxyribonucleic acid and protein content), (C) incubation in the absence of thymine (increased ribonucleic acid and protein/deoxyribonucleic acid content).

In normal log phase *E. coli* 15r- (condition A) exposed to 10,000 r of X rays deoxyribonucleic acid synthesis proceeded rapidly for 30-60 min (Fig 1). This was followed by a period in which no net synthesis was detectable. In other experiments in which survival was higher than that found in the experiment from which the data of Fig 1 were taken, renewed synthesis was sometimes seen by 90 min. The number of colony forming cells in the irradiated suspensions (10-25 per cent of the controls) remained constant or showed a slight decline during the first 30 min. A rapid increase then occurred that probably accounted for the renewed synthesis observed in some experiments.

When chloramphenicol was added to log phase cells (condition B1) ribonucleic acid and deoxyribonucleic acids continued to accumulate while protein synthesis was largely inhibited¹. Such cells washed free of the antibiotic and re-incubated in thymine supplemented minimal medium showed a delay of approximately 30 min before net deoxyribonucleic acid synthesis resumed (Fig 1). When the washed cells treated with chloramphenicol were exposed to 10,000 r of

Fig 1. The influence of prior chloramphenicol treatment on subsequent deoxyribonucleic acid synthesis. Prior to treatment with 10,000 r of X rays log phase *E. coli* 15r- cells were incubated for 1 hr under the following conditions: (A) normal log phase cells (condition A of text), (B) condition B and then exposure to 10,000 r, (C) condition B1 then exposure to 10,000 r, (D) condition B2 then exposure to 10,000 r, (E) condition C then exposure to 10,000 r.

X rays and then resuspended in thymine-supplemented medium no net increase in deoxyribonucleic acid content was observed during the 2 hr the cultures were studied (only the first 90 min are shown in Fig 1). A similar result was found for cells washed free of thymine prior to incubation in thymine free minimal medium to which chloramphenicol has been added (condition B2). During such incubation only ribonucleic acid was observed to accumulate in large amounts during the 1 hr exposure to the antibiotic¹. As seen in Fig 2 deoxyribonucleic acid synthesis in such cells was completely suppressed after X ray exposure.

Log phase cells washed free of thymine and then re incubated for 1 hr at 37° C in thymine free minimal medium (condition C), showed a marked increase in ribonucleic acid and protein nitrogen while deoxyribonucleic acid synthesis was essentially nil¹. This was the 'unbalanced growth' reported for this strain of *E. coli* by Barner and Cohen⁴. Following this treatment the cells after harvesting and washing at ice bath temperature, appeared to be 'synchronized' with respect to deoxyribonucleic acid synthesis (Fig 2). The deoxyribonucleic acid nearly doubled in 30 min. This was followed by a period of reduced deoxyribonucleic acid synthesis before a new rate of deoxyribonucleic acid accumulation was seen. X irradiation did not greatly alter the synthesis during the initial doubling period (Fig 2). However, after this initial burst no further increment was found during 120 min of observation. The loss of acid insoluble deoxyribonucleic acid observed in the irradiated cell culture after 60 min was due to lysis of a portion of the cells as reflected in a decreased turbidity of the cultures as well as a reduction in the harvested cell yield (not shown). The surviving cells did not grow at

Fig. 2 The effect of thymine starvation during chloramphenicol exposure on subsequent deoxyribonucleic acid synthesis. Prior to treatment with 10,000 r of X-rays, log-phase *E. coli* 15T- cells were incubated for 1 hr under the following conditions: ●—●, incubation in the absence of thymine (condition C of text), ○—○, condition C, and then exposure to 10,000 r, ●---●, exposed to chloramphenicol in the absence of thymine (condition B2), ○---○, condition B2, and then exposure to 10,000 r

rapid rate to be reflected in the analysis during these 2 hr. It required more than 2 hr for dividing survivors to reach the initial level of unirradiated cells of the controls.

Thus, during the incubation in the absence of thymine (condition C), a radioresistant synchronization of deoxyribonucleic acid appeared to have occurred. Similar treatment did not synchronize ribonucleic acid or protein synthesis⁶. The addition of chloramphenicol to such cells prevented the development of the radioresistant system synthesizing deoxyribonucleic acid. It is also apparent that the addition of chloramphenicol to log-phase *E. coli* 15T- incubated in the presence of thymine resulted in a physiological state such that deoxyribonucleic acid synthesis did not occur immediately after removal of the antibiotic. Cells in this physiological state could not synthesize deoxyribonucleic acid until a radiosensitive process had been initiated. Although the mechanism whereby chloramphenicol brings about this effect is unknown, it is tempting to speculate that the antibiotic-induced inhibition of protein synthesis was involved. The protein (and/or ribonucleic acid) synthesized in a given time period (in the presence or absence of net deoxyribonucleic synthesis) may be a necessary prerequisite for subsequent deoxyribonucleic acid synthesis. One may envisage this protein as being involved in the formation of a template⁷⁻¹⁰ or as specific enzymes perhaps similar to the polymerases described by Kornberg and collaborators¹¹ which were found to be capable of *in vitro* deoxyribonucleic acid synthesis. Additional experiments planned may provide further insight into the true nature of the radiosensitive process inhibited by chloramphenicol.

ults with irradiated *E. coli* 15T- correlate the findings of others in plant¹² and

animal^{13,14} studies that there is a radiosensitive process involved in deoxyribonucleic acid synthesis, which is not the deoxyribonucleic acid replication system itself. The radiosensitive process occurring prior to actual deoxyribonucleic acid synthesis may involve protein synthesis as suggested from the results presented here. Log- or stationary-phase cell suspensions when exposed to X-rays contain organisms in various phases of their division cycle. One may speculate that there occurs, in normal growth of individual cells, a phase such that the products of the radiosensitive process are exhausted and must be synthesized anew before deoxyribonucleic acid replication can proceed. If most cells of an exposed population were in the active deoxyribonucleic acid synthesizing (radioresistant) phase they would continue to make deoxyribonucleic acid until a predetermined level would have been reached. Therefore at doses of X-rays in which most of the population no longer were colony-forming cells a good amount of deoxyribonucleic acid as well as ribonucleic acid and protein synthesis would occur⁵. The extent of deoxyribonucleic synthesis would be determined by the length of the deoxyribonucleic synthetic period relative to that of the sensitive pre-synthetic phase. In a log-phase population most cells would be in the deoxyribonucleic acid synthesizing phase if this period occupied most of the division cycle of the cell. Based on this model our results would suggest that most log-phase cells are not in the radiosensitive period since irradiated populations increased significantly their deoxyribonucleic acid levels upon reincubation. The radiosensitive pre-synthetic process, having been inhibited by radiation exposure, would no longer function and thus deoxyribonucleic acid synthesis would come to a close if it is assumed that the radiosensitive process is permanently inhibited by irradiation. When sufficient numbers of survivors were present these would grow at a rate reflecting their physiological state prior to exposure and eventually produce measurable amounts of deoxyribonucleic acid. If the number of survivors were high enough and exhibited little lag upon resuspension in a complete growth medium they would produce sufficient amounts of deoxyribonucleic acid to be measurable soon after exhaustion of deoxyribonucleic acid synthesis in dying cells. Thus the termination of deoxyribonucleic acid synthesis in dying or dead cells would be masked by the dividing viable cells. At higher doses of X-irradiation deoxyribonucleic acid synthesis may be completely suppressed by the destruction of the radioresistant deoxyribonucleic acid synthesizing mechanism itself⁵.

GEOPHYSICS

Great Earthquakes and the Astronomical Positions of Uranus

THANKS to the excellent collection of uniform data of earthquakes given by Gutenberg and Richter¹, it is now easily possible to study statistically the influence of different factors on earthquakes. In the course of a study of tidal effects on earthquakes², the astronomical positions of the planets have also been taken into account and a remarkable correlation between the positions of Uranus and the moment of great earthquakes has been established for a certain period. Gutenberg and Richter's data of all earthquakes equal or greater than magnitude 7½ have been used. The investigations will be published in detail later, but here attention is directed to the results concerning the position of Uranus.

A total of 134 earthquakes has been investigated in this fairly significant amount of cases has been found, where Uranus was very near its upper or lower transit of the meridian of the epicentre in the time of great earthquakes. Closer investigation showed that this occurred especially during the years 1004 where Gutenberg-Richter's data start, and also 1005 and 1006. The results for this period are given

in Table 1, which contains the data for the earthquakes and also the Right Ascension of the meridian of the epicentre at the time of the earthquake and the position and the meridional distance in Right Ascension of Uranus at that time. The latter data have been divided into two groups. Group I contains all the cases when Uranus is within a distance of $\pm 1h$ from upper or lower transit through the meridian. Group II comprises all cases with greater meridional distances, that is, within $\pm 1h$ to $\pm 6h$. The probability of Uranus being found in group I is one sixth of the total cases and that for group II is five-sixths of the total, if the distribution of the times of the earthquakes is entirely by chance. As Uranus completes each day very approximately all the possible meridional distances, there occurs within the period of 1 000 days, represented in Table 1 a total of 2,180 transits (upper and lower). Therefore if the times of occurrence of earthquakes are distributed by chance, a uniform distribution of the positions of Uranus can be expected. This is corroborated by the fact that the positions of the Sun or the Moon show no significant deviation from pure chance. For example, in Table 1 the Sun is found to be five times near transit which is very near the expected value for chance distribution of group I. But the result for Uranus is quite different and unexpected.

Of 23 cases, listed in Table 1, not less than 15 belong to group I and only 8 are in group II. The expected number for group I would be 3.8. Application of the chi-square test gives $\chi^2 = 41$, with Yates's correction $\chi^2 = 37$, that is, for one degree of freedom, a probability much less than 0.0001 for its being a chance distribution. The deviation is therefore highly significant. The fact should be stressed that Table 1 is complete, that is, it includes all the earthquakes of magnitude equal to or greater than $7\frac{1}{2}$ (including intermediate and deep shocks) which occurred during this period.

Two points must be cleared up. First, for how long does the period extend with this marked correlation, and secondly, how far is it characteristic of Uranus? Or does the period include some other cosmic direction which only accidentally coincides with the position of Uranus during this period of observation? Regarding the first point, it can be stated that after 1906 the correlation becomes less significant, but it remains greater than average. As an example, Table 2 shows the meridional distance of Uranus for three remarkable earthquakes of later years, when the position of Uranus had already greatly changed. No. 1 is the Tokyo earthquake in the course of which 100,000 people were killed and 500,000 houses were destroyed. No. 2 is the second largest earthquake of the first half of this century (the greatest is No. 17 in Table 1) and No. 3 is the famous Assam earthquake (*Nature*, 167, 128, 1951). In each of these cases Uranus is near the meridian—not farther away than 30 min from its lower transit. There is a certain difficulty in extending the investigation back to the years before 1904, as in many cases the epicentres are either not known or only very inaccurately. A collection of data has been given by Gutenberg³. Using his data and limiting the investigations to all cases where the epicentres are known with an accuracy of at least $\pm 5^\circ$ of their geographical position, their number is 23 for the years 1900–3. In eight cases the position of Uranus is in group I, the expected number is 3.8. Therefore, the correlation extends back to 1900, but with diminished significance.

It should be mentioned that the years 1904–6 corresponded to a conspicuous maximum of energy release by the Earth through earthquakes. According to Gutenberg³, the annual release during each of these years is 10.6, 22.2 and 34.1, against 6 in 1903 and 4.9 in 1907 (in units of 10^{24} ergs).

So far as the role of Uranus is concerned, it may be noted that the planet was nearly symmetrically opposed, during these years, by Neptune and Pluto and went into direct opposition to Neptune in 1906. The cases of 1906 are therefore also cases where Neptune was simultaneously near its transit at the times of the earthquakes. An opposition of Sun, Venus and Mars to Uranus also occurred at the time of the Tokyo earthquake (Table 2).

The correlation cannot be explained by a tidal effect, since the statistical investigation for all the great earthquakes ($M = 7\frac{1}{2}$) during 1904–50 in regard to the absolute and relative positions of the Sun and the Moon give no indication of a significant deviation from chance distribution. The tidal forces of the planets are extremely small compared with those of the Sun and the Moon. That the accumulated stresses within the Earth's crust are released at times which, at least for a period of several years, are strongly correlated with certain positions of Uranus may,

therefore, not be a relationship of cause and effect in the usual mechanical sense.

Air Density in the Upper Atmosphere from Satellite Orbit Observations

From the rate of change of period of a satellite, it is possible to derive the density of the atmosphere at the altitude of the perigee of the orbit. Now that some ten successful satellite launchings have taken place, giving orbits with various perigee heights, the variation of air density with height can be derived over a considerable range of altitude. Many perigee heights have been less than 230 km, the exceptions being *Explorer IV* (1958 ζ) at 260 km, *Explorer I* (1958 α) at 365 km, *Vanguard I* (1958 β 2) at 656 km, and the recently launched *Vanguard II* (1959 α) at 558 km. The air density at greater heights is therefore less well established. From an analysis of data from six different satellites, the smoothed set of values in Table 1 has been derived. The accuracy, estimated by fitting a quadratic variation with height to the logarithm of the density, is of the order of 20 per cent at the lower heights and 50 per cent at the greater heights.

Table 1. VALUES OF AIR DENSITY DERIVED FROM OBSERVATIONS ON SATELLITES 1957 α , β AND 1958 α , β , γ AND ϵ

| Height (km) | Air density (gm/c.c.) | Height (km) | Air density (gm/c.c.) |
|-------------|-----------------------|-------------|-----------------------|
| 150 | 1.2×10^{-12} | 450 | 3.8×10^{-16} |
| 200 | 3.8×10^{-13} | 500 | 1.9×10^{-16} |
| 250 | 1.4×10^{-13} | 550 | 9.0×10^{-17} |
| 300 | 5.0×10^{-14} | 600 | 5.3×10^{-17} |
| 350 | 2.0×10^{-14} | 650 | 3.2×10^{-17} |
| 400 | 8.4×10^{-15} | 700 | 2.0×10^{-17} |

Above 300 km, the values of air density depend chiefly on the *Explorer I* and *Vanguard I* observations. After this analysis had been carried out, the rate of decrease of period for these two satellites increased comparatively rapidly to a new nearly constant value. The increase amounted to a factor of 1.51 for *Explorer I* and to a factor of 2.52 for *Vanguard I*, showing the effect to increase with height. For *Vanguard I*, the slope of the period-time curve has recently returned to its original value, and the local time at perigee, while the slope had the greater value, ranged from about 12.00 hr to 18.30 hr. For *Explorer I*, the slope has also returned to its original value and is at present about to change again, the greater value being maintained for approximately the same range of local time as *Vanguard I*. If this change is attributed to a variation in air density, then the values in Table 1 need to be increased by the above factors when local time lies in the range 12.00–18.30 hr.

The scale height of the atmosphere H is the height interval over which the density changes by an exponential factor. Values for H in the region of 200 km have been deduced in the following three ways.

(1) From the above density-height profile H is obtained¹ as $46 (\pm 5)$ at 200 km. H increases with

bought and values of 52, 61, 72 and 89 km are obtained for 300, 400, 500 and 600 km altitude, but the observations are too scanty to enable the accuracy of these values to be estimated. The gradient of the scale height at 200 km is obtained as 0.06 km/km.

(2) From the decrease in perigee distance. From *Explorer III* H is obtained³ as $39 (\pm 9)$ km at 180 km, and from *Atlas* (1958 ζ) as 36 km to within a few kilometres for the same altitude.

(3) From the change in perigee height due to the Earth's equatorial bulge⁴. This method is suitable for satellites at approximately the molination of the Russian artificial satellites, when the perigee moves slowly around the orbit and a significant part of the change in perigee height arises from the Earth's equatorial bulge. From *Sputnik II*, H is obtained⁵ as $36 (\pm 15)$ km. For *Sputnik III* rocket (1958 δ_1), methods 2 and 3 lead to inconsistent values.

A few rocket measurements of air density at the 200 km. level exist for comparison with the satellite values. A value of 2.7×10^{-12} gm./o. at 200 km has been reported⁶ from a U.S.S.R. rocket firing at 50° N. The Viking 7 flight in August 1951 at White Sands, New Mexico, gave⁷ 1.4×10^{-12} gm./o. (to within a factor of 2) for the density and 43 km. for the scale height at 200 km. The latitude of White Sands is 30° N., and most of the observations upon which Table 1 is based refer to perigee latitudes between 30° N. and 33° S. The agreement between the scale heights is very close and that between the densities is just acceptable. On the other hand, an *Aerobee H* fired in July 1957 at Fort Churchill, latitude 50° N., gave⁸ 7.0×10^{-12} gm./o. (± 30 per cent) for density and 94 km. for scale height at 200 km. altitude. A considerable latitude effect is therefore indicated at higher latitudes and there is clearly a need for satellites with orbital inclinations near 90°, so that densities may be determined at the highest latitudes. Two further Fort Churchill firings have given⁹ a winter day value of 3.0×10^{-12} gm./o. and a winter night value of $1.3 \pm 0.6 \times 10^{-12}$ gm./o. at 202 km.

At the 200 km. altitude, the scale height seems to be in the region of 40 km. for equatorial and sub-tropical latitudes. The corresponding temperature for an assumed molecular weight of air of 25 would be $1,100^\circ$ K.

The results given here agree closely with those of D. G. King Holm¹⁰.

Acknowledgment is made to the Smithsonian Institution, the Naval Research Laboratory Washington, and the Royal Aircraft Establishment Farnborough for their issues of orbital data on which these calculations have been based.

PHYSICAL SCIENCES

A Special Case of the Superposition of Crystal Plates between Crossed Polars and its Bearing on the Microscopy of Cellulosic Fibres

When monochromatic light is passed at perpendicular incidence through two superposed and differently orientated transparent crystal plates between crossed polars the intensity of the light transmitted by the analyser relative to that of the light entering the plates is given by the following expression, as was shown by Fresnel

$$I = -\sin^2(\psi_1 - \psi_2)\sin^2\psi_1\cos^2\psi_2\sin^2(\delta_1/2) + \sin^2(\psi_1 - \psi_2)\cos^2\psi_1\sin^2\psi_2\sin^2(\delta_2/2) + \cos^2(\psi_1 - \psi_2)\sin^2\psi_1\sin^2\psi_2\sin^2(\delta_1/2 + \delta_2/2) - \sin^2(\psi_1 - \psi_2)\sin^2\psi_1\sin^2\psi_2\sin^2(\delta_1/2 - \delta_2/2) \quad (1)$$

where I is the relative intensity as just defined, ψ_1 , ψ_2 are respectively, the angles made by the corresponding vibration directions of the plates (that is, either the 'slow' or the 'fast' directions) with the vibration direction of the polarizer and δ_1 , δ_2 are the phase differences produced by the plates. (The expression ignores any reduction in the intensity due to absorption by the analyser, such as occurs in polaroid, but for a given analyser this reduction is by a constant factor and does not affect the arguments which follow.) If the plates are of equal thickness and birefringence, $\delta_1 = \delta_2 = \delta$ and the fourth term in the expression vanishes. If also we put 20 for the angle between the corresponding vibration directions say the 'slow' directions of the plates and α for the angle between the bisectrix of 20 and the vibration direction of the polariser (Fig. 1) the expression can be reduced to the form

$$I = 4\cos^2(20)\sin^2(\delta/2)\cos^2(\delta/2)\sin^2(2\alpha) - 4\sin^2(20)\cos^2(20)\sin^2(\delta/2)\cos^2(\delta/2)\cos^2(2\alpha) + 4\sin^2(20)\cos^2(20)\sin^2(\delta/2) \quad (2)$$

(This involves making use of the following equalities

$$(\psi_1 - \psi_2) = 20, \quad \psi_1 = (\alpha - 0) \quad \psi_2 = (\alpha + 0) \quad \sin^2(\alpha - 0)\cos^2(\alpha + 0) - \cos^2(\alpha - 0)\sin^2(\alpha + 0) = -\sin^2(40), \quad \sin^2\delta = \sin^2(2\delta/2) = 4\sin^2(\delta/2)\cos^2(\delta/2))$$

By differentiating I with respect to 2α , and equating to zero it can be shown that in the general case I has a minimum value when $\alpha = 0^\circ, 90^\circ, \dots$ etc., and a maximum value when $\alpha = 45^\circ, 135^\circ, \dots$ etc., that is that the pair of plates 'extinguish' when the bisectrix OB (Fig. 1) is parallel or perpendicular to the polarizer vibration direction OP , and shows maximum brightness when in the 45° positions.

Three special cases arise. Two of these are familiar in one $20 = 90^\circ$, so that the two plates exactly compensate one another and in the other $\delta = 0^\circ$, or $n \times 360^\circ$ where n is a whole number. In both these cases $I = 0$ for all values of α . The third case is that in which $\delta = 180^\circ$ or $(n \times 360^\circ) + 180^\circ$ and the purpose of this note is to draw attention to it since its consequences do not appear to be generally realized. In this case the first two terms of equation (2) vanish since they both contain $\cos^2(\delta/2)$ which is now zero. The intensity is given by the third term alone which does not contain α , and which simplifies to

$$I = 4\sin^2(20)\cos^2(20) = \sin^2(40) \quad (3)$$

since $\sin^2(\delta/2) = 1$. The intensity of the component which passes the analyser therefore remains constant as α varies, that is as the plates are rotated in unison.

in their own plane between the polars, as for example on the stage of a polarizing microscope, there are no 'extinction' (minimum intensity) positions. The reason for this is demonstrated geometrically in Fig 2. OP_1 and OP_2 are the 'slow' vibration directions of the plates, the latter being that for the upper plate, that is the one nearer to the analyser. OB is the bisectrix of the angle between these directions. OP is the vibration direction and amplitude of the light from the polarizer. Since $\delta = 180^\circ$, or $(n \times 360^\circ) + 180^\circ$, the light emerging from each plate must be linearly polarized, and have the same amplitude as that coming from the polarizer. By applying the ordinary construction we find that the vibration vectors of the light emerging from the lower and upper plates are OL and OH respectively, and $OH = OL = OP$. It can readily be proved that the direction of OH is independent of the angle $BOP(\alpha)$, and dependent only on the angle Pl, OP_1 , (2θ). The amplitude of the component which passes the analyser, OA' , therefore remains constant as the plates are rotated in unison.

If the plates be interchanged without changing the angle 2θ , so that OP_1 now refers to the upper plate, the vibration direction and amplitude of the light emerging from this plate is found to be OH' , which makes the same angle φ with the analyser vibration direction as OH , and thus gives the same amplitude OA' for the component which passes the analyser. (In conformity with this result, the expressions given above take no account of which plate is on top.)

By rotating the analyser so that its vibration direction becomes perpendicular to that of the light emerging from the upper plate extinction results, and this extinction is not relieved when the plates are rotated in unison. Thus if OH is the vibration direction of the light coming from the top plate, extinction is obtained by rotating the analyser through the angle $(90 - \varphi)$ to OE . This angle is related to 2θ as follows

$$\sin(90 - \varphi) = \cos \varphi = OA'/OH = \sin(4\theta) \quad (4)$$

(The last step in this relationship follows from equation (3), which gives the relative intensity, that is $(OA'/OP)^2$, as $\sin^2(4\theta)$. Thus $OA'/OP = OA'/OH = \sin(4\theta)$.) Equation (4) has two solutions, since 4θ can be either $(90 - \varphi)$, or $(90 + \varphi)$, the sines of which are equal.

Extinction can also be obtained by rotating the polarizer through the angle $(90 - \varphi)$, but in the opposite direction, thus bringing OH perpendicular to the analyser vibration direction.

The above case can only apply exactly for one wave-length with any given pair of plates for which it applies at all, but if this wave-length (which we will now refer to as μ_{180}) is near to the middle of the spectrum, a good approximation to the characteristic effects which have been described is obtained even when white light is used. This can be readily demonstrated by superposing cleavage strips of mica, for each of which μ_{180} is in the yellow or yellow-green, on the stage of a polarizing microscope which is illuminated with white light. On rotating the stage, no positions of minimum intensity can be distinguished (at least with the unaided eye). By turning either the analyser or the polarizer through a certain angle, extinction or near-extinction will be secured, and this will only be slightly relieved on rotating the stage. The reason for this behaviour is that the

vibration of the light emerging from the upper plate follows a very narrow ellipse for any wave-length within a considerable range on either side of λ_{180} , and the major axis of this ellipse corresponds to much the same vibration direction and amplitude as those of the linearly polarized light of wave-length λ_{180} .

The foregoing has a bearing on the polarization microscopy of cellulosic fibres, the spiral wall structure of which causes them to behave optically in a similar way to systems of superposed plates. When light is passed through a cylindrical fibre of this type, the angle between the 'slow' directions for the front and back walls (2θ in the above treatment) and the thickness presented to the light beam are of course not constant across the fibre, so that each vertical longitudinal section shows different optical effects. Flattened, ribbon-like fibres, such as those of dry cotton, however, approximate very closely to systems of two flat plates, except where they are twisted. Taking cotton, in which the spiral angle is considerable (ca 30° with respect to the fibre axis), as an example, the following observations may be made. In immature fibres the walls are very thin and δ is very much less than 180° . Between crossed polars such a fibre shows well-defined minima of intensity when its axis is parallel to the vibration directions of the polars, and it also behaves towards compensators as though its axis were a 'slow' direction of vibration. Among the thicker fibres of mature cotton, however, some will be found which show all the properties described above for the case $\delta = 180^\circ$, or approach this behaviour very nearly, at least along portions of their length. The behaviour of such fibres towards compensators is quite ambiguous, because over a large part of the spectrum the emergent light is approximately linearly polarized, with a vibration direction which is little affected by the position of rotation of the stage, as explained above.

Fig 1

Fig. 2

By means of equation (4) it should be possible to obtain at least approximate values of the spiral angle from measurements of the angle $(90 - \phi)$ made at the wave length λ_{00} . This wave length can be estimated roughly with the aid of suitable filters, or more accurately by means of a monochromator, as being that at which the closest agreement with the theoretical behaviour for the case $\delta = 180^\circ$ is obtained.

This case and its consequences are not dealt with in any of the publications on fibre microscopy with which I am familiar.

Birefringence of Montmorillonite Complexes

DURING a study of the optical properties of montmorillonite aggregates in salt solutions¹, some interest in preliminary observations were made on various aromatic complexes. These observations have now been followed up with the view of extending the use of optical data in characterizing clays.

The structures of various aromatic complexes of montmorillonite have been inferred from spacing measurements and one-dimensional Fourier syntheses². The monolayer complexes could be grouped into two classes, those where the plane of the ring was parallel to that of the silicate sheet (type A) and those where it was perpendicular (type B). Clearly, because the polarizability of the aromatic ring is usually much greater in the plane of the ring than perpendicular to it³, the preferred orientation of the interlayer molecules in aromatic complexes should profoundly affect the apparent birefringence of the mineral. Thus in type B complexes the effect of the interlayer molecules would be expected to reduce the strong negative birefringence of the silicate layers and even make some aggregates optically positive. In contrast, type A complexes would be

expected to be strongly negative. These expectations were strikingly confirmed when the birefringence of the nitrobenzene complex (type B) was found to be 0.003 (negative) as compared with 0.020 (negative) for the unexpanded mineral. An even larger effect was to be expected with quinoline which is more anisotropic than nitrobenzene⁴, and the orientation of the interlayer molecules is such as to increase greatly the polarizability of the complex perpendicular to the silicate sheets⁴. Measurement of its birefringence showed it to be 0.02 (positive). In contrast type A complexes were found to be strongly negative, for example, pyridinium montmorillonite (type A) was 0.024 (negative).

These large birefringence changes obtained with montmorillonite not only confirm the proposed orientation of the interlayer molecules but could be used to characterize clays in the same way as glycol and glycerol are used in X-ray diffraction analysis. For example, rapid assessment of clays for montmorillonite minerals is possible by measuring the changes in birefringence of aggregates on immersion in quinoline solutions. Where montmorillonite predominates, the optical sign is changed after treatment. Again, clays known to be homogeneous, but partially expanding and giving a complex X-ray diffraction pattern, have been rapidly and simply evaluated in terms of the percentage of expanding layers, from the change in birefringence in different solvents. When evaluation has been possible from X-ray results⁵ the agreement between the two methods has been excellent.

The preliminary part of this work was done while I held a Royal Society Exchange Fellowship 1957-59, with the Academy of Sciences U.S.S.R.

Electron Paramagnetic Resonance at 42° K. of γ -Irradiated Polymethyl Methacrylate and Polymethacrylic Acid

THE electron paramagnetic resonance spectrum given by polymethyl methacrylate after high-energy irradiation at room temperature consists of five lines, about 23 gauss apart, with intensities in approximately the ratios 1:4:6:4:1, with a weaker intermediate pattern of four lines, both closely centred on the electron spin g factor of 2.001^{1,2}. Since this spectrum is also given by free radicals trapped during the addition polymerization of methyl methacrylate^{3,4}, it has been postulated that it arises from trapped propagating radicals of structure, $-\dot{C}H_2-C(CH_3)(CO_2CH_3)_2$, the detailed explanations involving the exact conformation of these radicals^{5,6}. Both of the explanations put forward by Symons⁷ require that the methyl group bonded to the 'radical' carbon atom rotates rapidly so that its three protons interact equally with the unpaired electron. If one of these

explanations is correct, the hyperfine structure of the spectrum should alter when the temperature is lowered sufficiently. The rotation of the methyl group might change to a torsional oscillation, thus destroying the equivalence of the three methyl protons. If however the rotation remains free, at a temperature where only the lowest rotational level is populated, symmetry conditions will govern the occupation of the nuclear spin levels.

Laboratory-prepared samples of polymethyl methacrylate and polymethacrylic acid were gamma-irradiated at room temperature with doses of about 10^7 r using a cobalt source. Their spectra were measured at 77° K and 4.2° K with a 3,000 Mc/s spectrometer using low amplitude 100 c/s magnetic field modulation with phase detection to give the first derivative of the absorption spectrum.⁷ The samples were contained in Dewar vessels inserted into the microwave cavity. At 77° K both polymers gave the well-known spectrum (Fig 1). The spectra at 4.2° K (Fig 2) also consist of nine lines with essentially the same spacings, centred on $g = 2.00$. However, a marked change in the relative intensities of the lines has occurred. Polymethacrylic acid showed no power saturation at 4.2° K, but when the temperature was further lowered, broadening of the individual hyperfine components occurred at high microwave power. At 4.2° K the polymethyl methacrylate spectrum was considerably broadened at high microwave power, and the spectrum shown was obtained at very low microwave power. Owing to overlap it is difficult to make accurate estimates of the relative intensities of the hyperfine components. The absorption-curves obtained by graphical integration were fitted by patterns with relative intensities of approximately 1 2 3 4 5 5 4 5 3 2 1, for polymethyl methacrylate and 1 1 7 2 3 2 5 2 5 2 3 1 7 1, for polymethacrylic acid. The individual line widths are similar for all three spectra, and the decreased resolution at 4.2° K arises from the change in relative intensities.

The total wave function of the radical must be antisymmetric to exchange of nuclei, and if it were behaving as a free rotator with only the lowest level occupied, only antisymmetric nuclear spin functions would be allowed.⁸ Those states in which all nuclei are aligned either with or against the electron spin would be forbidden and the outermost hyperfine components would not be present. It is clear that this effect is not operating here.

Fig 1 First derivative of electron paramagnetic resonance spectrum at 77° K of γ -irradiated polymethyl methacrylate

Fig 2 First derivatives of electron paramagnetic resonance spectra at 4.2° K of γ -irradiated polymethacrylic acid (upper curve) and γ -irradiated polymethyl methacrylate (lower curve)

Explanations of these spectra based on non-rotation of the methyl group have been attempted. Since the total hyperfine splitting is unchanged, the sum of the coupling coefficients of the three methyl protons must be unchanged. These coupling coefficients must be multiples of the line spacing (11.5 gauss). There are two possible cases, corresponding to two positions of the methyl group which have one proton either in line with, or orthogonal to, the 'radical' carbon atom p orbital. When these are taken with either of Symons's suggestions regarding the coupling of the methylene protons^{4,6}, nine line spectra with the observed spacings are predicted, but it is not possible to obtain even an approximate fit to the observed intensity ratios.

I am indebted to W. H. Jennings for technical assistance, and to Dr. Walter Gordy for his interest. This research was supported by the Office of Ordnance Research, Department of the Army.

CHEMISTRY

Electron Spin Resonance and Divalency of Some Dithiocarbamates of the Coinage Metals (Cu, Ag, Au)

In a previous paper¹ one of us reported an investigation of the *N,N*-dialkylthiocarbamates of the univalent coinage metals, and in another² the reaction of the compounds in question with the corresponding thuram disulphides. Several of these compounds are not only of significant theoretical interest but they also play an important part in several branches of practical chemistry (for example, as ultra accelerators in rubber vulcanization, antioxidants in lubricants, in medicine for treatment of chronic alcoholism, etc.).

As divalent copper, silver and gold compounds all would be paramagnetic with electron configurations $3d^9$, $4d^9$, $5d^9$ respectively, it is possible to infer the existence of this oxidation state from a study of the electron spin resonance absorption spectra. This investigation gives, among other things, the first proof of the existence of the divalent oxidation state of gold.

X-ray investigations by Heese³ and Poyronol⁴ show that the copper compounds, $(R_2NCS)_2Cu$, form square planar complexes. It seems very likely that the corresponding silver and gold complexes have an analogous structure.

Fig. 1 shows typical spectra obtained from solutions of copper, silver and gold complexes. The spectra of the ethyl isopropyl (Fig. 1a) and methyl phenyl copper compounds are almost identical and have a g value of 2.046. The four hyperfine lines vary in width. This is typical for copper complexes and arises from insufficient averaging of the anisotropic resonance structure⁵. The high field line is so narrow (width about 4 gauss) that the hyperfine structure of the two copper isotopes copper 63 and copper 65 is resolved. The hyperfine separation of copper 63 is 7.4×10^{-3} cm⁻¹.

Fig. 1. Derivatives of electron spin resonance absorption curves recorded at room temperature. Microwave frequency about 9,500 Mc./s. The arrows indicate the resonance field for free electrons. Solvent benzene. (a) $(iso-C_4H_9)_2NCS_2Cu$; (b) $(iso-C_4H_9)_2NCS_2Ag$; (c) $(iso-C_4H_9)_2NCS_2Au$.

If silver(I) *N,N*-dialkylthiocarbamates are mixed with the corresponding thuram disulphides dissolved in benzene or chloroform, the solution immediately turns blue¹. The colour is most probably due to a divalent silver compound, the reaction may then be written schematically as

The electron spin resonance spectra of these solutions (Fig. 1b) definitely confirm the divalency of silver. In the same environment the general features of the electron spin resonance spectra of divalent copper and silver should be the same, and this was found to be so in an investigation by Bowers⁶. We obtained a doublet due to the hyperfine interaction of the two naturally abundant isotopes of silver both with nuclear spin of $\frac{1}{2}$. If the spectra are expanded it is just possible to see the hyperfine structure of the individual isotopes, silver 107 and silver 109 (nuclear magnetic moments -0.113 and -0.130 nuclear magnetons respectively). The line width is approximately 2.5 gauss. The widths of the two hyperfine lines differ slightly, and this can be explained in the same way as the line width variation of the copper compounds. The g value is 2.019 and the mean hyperfine separation is 2.7×10^{-3} cm⁻¹. The similarity of the g values of these and the corresponding copper compounds also indicates that the structures of the complexes are the same.

From chemical evidence the reaction between the gold(I) *N,N*-dialkylthiocarbamates and the corresponding thuram disulphides may be written schematically as follows⁷:

The reaction is rather slow. In a typical electron spin resonance experiment $RS Au^I$ and $RSSR$ dissolved in benzene separately showed no electron spin resonance absorption, but on mixing four lines of equal intensity appeared (Fig. 1c). The same spectrum was obtained by dissolving $(RS)_2Au^{II}$ ($RS = (C_2H_5)_2NCS_2$ or $(iso-C_4H_9)_2NCS_2$) in benzene. This resonance cannot be due to tervalent gold for the following reasons. No complex of the tervalent coinage metals (except CuF_2^{2+}) has been found to be paramagnetic. Also we have made preliminary static susceptibility investigations of some gold(III) *N,N*-dialkylthiocarbamates (both solid and in solution) which indicate that these compounds are diamagnetic. Furthermore, we could not detect any electron spin resonance absorption of the solid compounds. We also found by comparison with copper compounds that the intensity of the resonance absorption of the gold(III) compounds dissolved with an excess of thuram disulphide (to prevent the reversal of reaction 1), was at most 1 per cent of what one would expect if the resonance was due to tervalent gold. The electron spin resonance absorption of the dissolved gold(III) complexes decreased on adding more disulphide which should however increase the gold(III) concentration. Similarly if disulphide was added to a solution containing a large excess of the

gold(I) compound, the resonance signal stayed constant even though the gold(III) concentration was at least doubled

As it is impossible to explain the four equally intense lines in terms of hyperfine structure of free radicals we conclude that the resonance lines originate from divalent gold. The resonance data themselves give strong evidence for the existence of divalent gold compounds. The g value of the gold(II) complex is 2.040 which is close to those of the copper and silver compounds, and the hyperfine structure is consistent with the nuclear spin of gold-197 which is $3/2$. The hyperfine separation is $2.8 \times 10^{-3} \text{ cm}^{-1}$.

Further experiments including single crystal investigations are planned. We also hope to be able to clarify why the resonance line-width of the gold compounds is greater than that of the copper and silver compounds.

We wish to thank Profs. A. Fredga and K. Siegbahn for their interest in our work.

Phototautomerization of Cytosine Derivatives on Ultra-violet Irradiation¹

UNSTABLE products were formed from certain cytosine derivatives on ultra-violet irradiation. These products had a new band at $\sim 240 \text{ m}\mu$ and lacked the characteristic $\sim 270 \text{ m}\mu$ maxima of cytosine derivatives. The products were not only reconstituted to their original compounds in the presence of acid and base but also spontaneously reconstituted themselves on standing, as indicated by the reversion of the ultra-violet spectra². Therefore, in these respects the cytosines differ from the uracils^{1,3}.

Because of the phenomenon of reversibility, investigators had classified cytosine derivatives and uracil derivatives together as one group from the point of view of photochemical behaviour². However, the electronic configurations of the two types are distinctly different. Since in aqueous solution, 4-hydroxy groups exist predominantly in the ketonic form (II) and the 4-amino group in the amino form (I), the uracils have exocyclic double bonds ($\text{C}=\text{O}$) at C^4 while the cytosines have endocyclic double bonds ($\text{N}=\text{C}$)³. Consequently, the photochemical pathway of cytosines might be altogether different from that of uracils.

Indeed, Shugar *et al.*² in their excellent study of cytosine derivatives have shown that irradiation, whether carried out in acid (pH 1-2), in alkaline (pH 9-11), or in neutral solutions produced similar photoproducts, which spontaneously reconstitute on standing. Both Shugar *et al.* and Sinsheimer² postulate the formation of photoproducts involving the addition of water. Since the photoproducts which they postulate are known to be stable only around neutrality, the existence of these molecules is most unlikely at either an extreme alkaline or acid pH during or after irradiation. If these products were actually formed, the decrease of optical densities during irradiation should have been similar to that seen upon thymine irradiation⁴. However, irradiation of cytosines at either an extreme alkaline or acid pH still gave reversible products instead of irreversible products, thus leading us to the conclusion that the unstable product probably is not a hydrated cytosine.

Irradiation of cytosine in buffered (pH 7) solution did not give a reversible product. However, irradiation in non-buffered solution gave a reversible product. Similar reversible products were produced from cytidine and cytidylic acid in either buffered or non-buffered solution. This indicated that when N^1H (N^1H) is not substituted, the salt effect from the buffer suppresses the formation of the reversible product. Therefore, it is suggested that $\text{N}^1(\text{N}^3)$ is probably involved in this photochemical change. (Synthetic $\text{N}^1(\text{N}^3)$ substituted cytosine derivatives behave similarly to that of cytosine. Using structural isomers we are now investigating the basis of this discrepancy.)

The decrease of optical densities at $270 \text{ m}\mu$ with a simultaneous increase at $240 \text{ m}\mu$ does not necessarily indicate the formation of dihydro derivatives, because these reduced compounds do not exhibit ϵ_{max} at any wave-length longer than $230 \text{ m}\mu$ ⁵.

On close examination of the absorption spectrum at neutral pH there is apparently a shoulder at $\sim 240 \text{ m}\mu$ besides the principal $\sim 270 \text{ m}\mu$ maxima. Therefore, the so-called new maximum at $\sim 240 \text{ m}\mu$ probably represents the increase of the optical density at the shoulder for that particular component structure.

From the above evidence, a tautomerization by irradiation seemed most likely to us. Indeed such an unstable tautomer (I^*) as shown involves $\text{N}^1(\text{N}^3)$ in the tautomerization. It is not a dihydro derivative resulting from a hydration product of cytosine. The shift from $270 \text{ m}\mu$ to $240 \text{ m}\mu$ is probably due to the change of a straight conjugation to a cross conjugation of the chromophore. The higher extinction at $240 \text{ m}\mu$ is probably due to the separation of charges in a molecule. Furthermore, barbitol derivatives, which have chromophores similar to that of the tautomer, have the ϵ_{max} at $240 \text{ m}\mu$ ⁶. In the dark the unstable

tautomer should revert to their most stable form, having the original spectra.

In order to demonstrate this tautomerization or isomerization, cytosine, cytidine and cytidylic acid were irradiated respectively both in buffered and non-buffered solutions. It will be evident from Figs. 1 and 2 that

isobestic points are present indicating that isomerization must have occurred? Irradiation of cytosine in buffered solution did not give an isobestic point therefore an irreversible product was formed. The spontaneous isomerization rather than the reversibility of the compounds of spectra in acid and base was the most interesting phenomenon about these observations. It indicates that an excited molecule can result from the absorption of photo energy and that this energy can be released slowly in another form, possibly available for chemical changes, without other influences, such as enzymes, heat, acidity etc. The apparent half life of the irradiated cytosine, cytidine and cytidylic acid are 50, 30 and 200 min, respectively.

Fig 1

Fig 2

The above results raise the question of the possible part that this phenomenon might play in biological systems.

This work was accomplished under the Common Contract AT(30-1)911 of the generous gift of Commission with the Physiology Department Biochemistry University School of Medicine. I wish to thank M. Apicella, L. A. Johnson and M. Monyos for able assistance.

Isotopic Composition of Boron

In a recent communication¹ it was concluded that a boron 11/boron 10 ratio of 4.00 approaches the true natural abundance ratio much more closely than the presently accepted value of 4.31. This value of 4.00 had been obtained from the mass spectra of boron hydrides and other volatile compounds.

Using a Metrovick mass spectrometer designed for the surface ionization of solids from a filament source and working with borax, we have obtained consistent results within the range 4.06-4.09 for the boron 11/boron 10 abundance ratio.

Stoichiometry of Bismuth Telluride and Related Compounds

Bismuth telluride, bismuth selenide and antimony telluride are being actively studied as semiconductors for thermoelectric cooling.¹ After purification by zone melting these materials do not exhibit intrinsic properties.² C. B. Satterthwaite and R. W. Ure³ have shown by electrical measurements that in the case of bismuth telluride there is a slight difference between the composition corresponding to the maximum of the liquidus curve and the stoichiometric composition. Electrical properties are sensitive to physical imperfections and their interpretation in terms of chemical composition is thus open to criticism.⁴

By using a sensitive method of differential thermal analysis we have found it possible to determine the composition corresponding to the maximum in the liquidus curve. The principle of this method is the use of the fact that for this composition the solid melts congruently whereas, for slightly different compositions it yields, after a suitable heat treatment, a mixture of two solid phases having different solid transition points.

Bismuth telluride containing excess tellurium forms an eutectic⁵ melting at 413°C and excess bismuth gives rise to a peritectic reaction⁶ at 540°C. Bismuth

Determination of Magnesium in Blood Serum by Atomic Absorption Spectroscopy

THE present lack of detailed knowledge of the function of magnesium in the human body is due partly to the lack of rapid and reliable methods for its routine estimation in small quantities of biological materials. Recently, Hunter¹ has devised a method for determining calcium and magnesium in blood serum by titration with murexide and with 'Eriochrome T'. It uses only 0.2 ml. of serum, but has

the disadvantage of requiring prior removal of protein by coagulation or ashing, and even then the magnesium is estimated indirectly by the difference of the two titrations. Methods for determining magnesium directly normally require removal of calcium also.⁴⁻⁶ The flame photometer method of Davis⁴ requires removal of protein followed by precipitation of the magnesium by 8-hydroxyquinoline.

It has been pointed out⁴ that atomic absorption spectroscopy⁷ can be used for the determination of magnesium in the ash from blood serum, since interference by sodium, potassium, calcium and phosphate is negligible.

I have recently⁸ described the determination of magnesium by the atomic absorption method, measurements can be made in solutions containing water, in salt of ethylene diamine, results reported here are made by diluting since only 2.5 ml of solution is used for determinations and with little sacrifice of accuracy in estimating magnesium. Most of the existing methods

The solution, 10 cm air-acet and absorption 2852 Å. was measured with solutions of magnesium.

* Freeze-dried bovine serum (Chemical supplied by Clinton Laboratories, Los Angeles). The magnesium values are higher than those for most bovine sera.

In view of the chemical and manipulative errors likely to be incurred in the preparation of such dilute solutions (~1 p.p.m.) by methods (b) and (c) the agreement is considered satisfactory, and the magnesium values obtained by direct dilution are probably more reliable than those obtained by the other methods. Duplicate readings on the same solution seldom differed by more than 2 per cent. Recovery of added magnesium was 100–102 per cent.

Although the present work was carried out with the air-acetylene flame, an air-coal gas flame is also satisfactory, and we are at present developing a very simple instrument which will determine magnesium in blood serum.

A fuller account of the present work will be submitted to *Analytical Chemistry*.

I am indebted to Mr E. Mason of the Commonwealth Serum Laboratories for a generous gift of horse serum and to Miss B. Splatt of the Biochemistry Department, Royal Melbourne Hospital, for the specimens of human serum.

BIOCHEMISTRY

Action of Trypsin on α -Carbomethoxy-L-lysyl-L-serylglycine and its O-Phosphorylated Analogue

The occurrence and isolation of phosphorylated peptides from enzymic hydrolysates of casein have already been reported.¹ These peptides exhibit unusual resistance to further proteolytic action, a fact which has been correlated with the existence of O-phosphorylated serine residues in their molecules. In order to investigate further the resistance of such peptides to the action of trypsin, certain synthetic peptide substrates suitable for this enzyme have been tested. Thus α -carbomethoxy-L-lysyl-L-serylglycine and α -carbomethoxy-L-lysyl (O-phosphoryl)-L-serylglycine were synthesized as follows:

α -Carbomethoxy (α -carbomethoxy)-L-lysine (I) was prepared from α -carbomethoxy-L-lysine in a similar manner described for the carbomethoxy isomulin derivative.² The oily product thus obtained was coupled by the mixed carbonyloxy-carbonic anhydride procedure with L-serylglycine³ (II) to give α -carbomethoxy (α -carbomethoxy)-L-lysyl-L-serylglycine (III) in 50 per cent yield, melting point 204° C. Analysis calculated for $C_{18}H_{28}N_4O_8$, N 11.2, found, N 11.1. When α -tosyl (α -carbomethoxy)-L-lysine, melting point 115–117° C., or the corresponding α -benzoyl derivative, melting point 110° C., were used, the coupling did not proceed satisfactorily, probably due to steric hindrance.⁴ Hydrogenolysis⁵ of III produces α -carbomethoxy-L-lysyl-L-serylglycine (IV), $[\alpha]_D^{25} = -28.0^\circ$ (c 0.78 in water). Analysis calculated for $C_{11}H_{18}N_4O_8$, $2H_2O$, N 14.1, found, N 13.0. Compound II was treated with benzyl alcohol in the presence of *p*-toluenesulphonic acid to give L-serylglycine benzyl ester *p*-toluenesulphonate (V) in 90 per cent yield, melting point 180° C. Analysis calculated for $C_{17}H_{24}N_4O_8$, N 6.5, found, N 6.2. The ester V was condensed with I by the anhydride procedure to afford α -carbomethoxy (α -carbomethoxy)-L-lysyl-L-serylglycine benzyl ester (VI) in 50 per cent yield, melting point 186–188° C., $[\alpha]_D^{25} = -17.0^\circ$ (c 1.5 in acetic acid). Analysis calculated for $C_{24}H_{36}N_8O_{10}$, C 59.30, H 6.52, N 9.7, found, C 59.4, H 6.7, N 9.5. To eliminate the side reaction with the hydroxyl group of serine, the ester V was dissolved in tetrahydrofuran/water (6/1) in the presence of two equivalents of triethylamine and then added to the anhydride solution.

Hydrogenolysis of VI produces IV with the same optical rotation. Coupling of I with V by the carbodimide method gave VI with melting point 185–186° C. Phosphorylation of VI with diphenylphosphoryl chloride⁷ in anhydrous pyridine resulted in the production of an amorphous product, which analysis suggested was a mixture of O-phosphorylated and unphosphorylated peptide derivative, although 50 per cent excess of the chloride was used. Compound VI dissolved in anhydrous pyridine and recovered after 2 hr, showed almost no change of its optical rotation.

Removal of protecting groups from the amorphous product by hydrogenolysis in the presence of palladium on charcoal, gave a mixture in which the monophenyl derivative predominated. Final removal of this was then attempted by further hydrogenolysis in the presence of platinum as the catalyst. Following paper electrophoresis in pyridine-acetate buffer, pH 5.5, revealed three ninhydrin-positive spots. The most intense and anodically fast moving one corresponded to the phosphorylated peptide. The desired product α -carbethoxy-L-lysyl-(O-phosphoryl)-L-seryl-glycine (VII), $[\alpha]_D^{25} -23.6^\circ$ (c 1 in water), was isolated by anion-exchange chromatography (Strid, L., unpublished work). Paper electrophoresis revealed one spot. Analysis calculated for $C_{14}H_{27}N_4O_{10}P$, N 12.6, P 7.0, found, N 12.05, P 7.3.

Compounds IV and VII were respectively incubated with trypsin in 0.2 M *tris*(hydroxymethyl) amino-methane hydrochloride buffer, pH 8.25, at 25° C. Qualitative analysis of hydrolysis products, on the other hand, was carried out by paper chromatography in butanol/acetic acid/water (4:1:5) system. The course of reaction was also followed by colorimetric analysis with ninhydrin reagent⁸. To this end, aliquots were withdrawn at different time intervals, mixed with 0.2 M citrate buffer, pH 5, at 5–6° C and then analysed.

As is indicated in Fig. 1, a phosphoryl residue attached to the hydroxyl group of serine renders the lysylserine peptide bond resistant to tryptic action. Paper chromatography of the incubation mixture of VII with trypsin also supported this conclusion. On the other hand, the incubation mixture of IV revealed two spots corresponding to α -carbethoxy-L-lysine

Fig. 2. Hydrolysis of O-phosphorylated L-carbethoxy-L-lysyl-L-seryl-glycine (0.01 M) with intestinal alkaline phosphatase (0.1 mgm./ml, crude preparation Lot 1105 Mann).

and L-seryl-glycine respectively.

The effect of alkaline phosphatase on α -carbethoxy-L-lysyl-(O-phosphoryl)-L-seryl-glycine at pH 9.5 (0.1 M triethylamine-carbon dioxide buffer) at 25° C is shown in Fig. 2. The amount of phosphorus liberated was determined by the modified method of Beerenblum and Chain⁹.

A Micromethod for the Polarographic Determination of Serine

THE serological behaviour of red blood cells is known to be altered by treatment with dilute solutions of potassium periodate. There is also some evidence that during the interaction of potassium periodate solutions with red blood cells, measurable quantities of periodate ion are consumed¹. While investigating the consumption of periodate ions by red blood cells, a method for the determination of relatively small amounts of serine was developed.

Malaprade² has described how compounds containing adjacent hydroxyl groups as well as hydroxy-amino-acids are oxidized by periodate ion. Based on this observation, several methods have been devised for the determination of serine by means of the periodate ion^{3–5}. These methods, however, including that of Boyd⁴ and Bambach⁵ based on the polarographic determination of formaldehyde formed by the action of the periodate ion and separated by

Fig. 1. Hydrolysis of O-phosphorylated and unphosphorylated α -carbethoxy-L-lysyl-L-seryl-glycine (0.01 M) respectively with trypsin (0.003 mgm N/ml, crystallized twice, 50 per cent $MgSO_4$, Lot 3388 Mann) in 0.2 M *tris* buffer, pH 8.25 at 25° C.

* Chl, Chloramphenicol, 20 μ gm/ml, 6AU, 6-aza uracil, 5 mgm./100 ml. Following exposure to ultra-violet the suspensions were incubated in minimal medium with the supplement indicated. The cells were removed from chloramphenicol by rapid centrifugation and resuspension in chloramphenicol free medium. The 6-aza uracil inhibition was reversed by addition of uridine to the medium. The auxotrophic strains were held following exposure to ultra-violet either with or without the appropriate growth supplement. In the case of cells without the required supplement, the supplement was added after lapse of the time indicated.

† Deoxyribonucleic acid synthesis resumed after 150 min incubation

Ultra-violet light induces a lag in the synthesis of deoxyribonucleic acid in *E. coli*. An investigation of the metabolic basis of this lag has been carried out, utilizing specific inhibitors of protein and ribonucleic acid synthesis and also auxotrophic strains requiring uracil, thymine or certain amino-acids (Table 1). These findings suggest that ribonucleic acid and protein synthesis (but not deoxyribonucleic acid synthesis) are required for reparation of the deoxyribonucleic acid synthetic system after damage by irradiation with ultra-violet, they are thus in agreement with recent reports^{9,10}

Table 2 EFFECT OF BLOCKAGE OF RIBONUCLEIC ACID AND PROTEIN SYNTHESIS ON SURVIVAL OF *Escherichia coli* STRAIN B FOLLOWING EXPOSURE TO ULTRA-VIOLET LIGHT

Ultra-violet dose was 2,395 ergs/mm². The suspension contained 1.4×10^8 colony forming bacteria per ml before exposure to ultra-violet. Survivors upon immediate plating following exposure were 6.0×10^4 per ml

| Post-irradiation treatment* | | Survivors ($\times 10^4$) per ml with incubation time (min) before plating | | |
|-----------------------------|-----------------|--|-----|-----|
| Incubation Medium | Added at 40 min | 40 | 120 | 160 |
| A M—N | — | 8 | 43 | 302 |

| I M—N+AA | 6AU | 8 | 116 | 480 |
| J M—N+AA+6AU | — | 7 | 11 | 17 |
| K M—N+AA+Chl | 6AU | 4 | 6 | 7 |
| L M—N+AA+6AU | Chl | 8 | 10 | 10 |

* M—N, minimal with ammonium sulphate deleted, Chl, chloramphenicol, 20 μ gm/ml, 6AU, 6-aza uracil, 5 mgm/100 ml, AA, casein hydrolysate, vitamin free, 2 mgm per ml

Table 2 shows a marked increase in survival of *E. coli* strain B with incubation in minimal medium from which the nitrogen source is deleted. The addition of amino-acids to this medium prevents the recovery observed (F). Further, the addition of chloramphenicol or 6-aza uracil to the nitrogen free cultures interferes with recovery (B, C). If, however, chloramphenicol or 6-aza uracil is added after 40 min incubation (D, E) recovery occurs. These results suggest that the recovery promoted by the M—N medium is dependent on both ribonucleic acid and protein synthesis within the first 40 min of incubation following exposure. It is obvious that this synthesis must be minor in quantity since no nitrogen source is present in the M—N medium. It seemed plausible that the recovery promoted by the M—N medium results from the prevention, due to the nitrogen deficiency, of 'unbalanced growth'¹¹ during the period required for reparation of the deoxyribonucleic acid synthetic system. This hypothesis is supported by the finding that either chloramphenicol or 6-aza uridine, if added to the medium containing amino-acids (F) after 40 min incubation following exposure to ultra-violet, promotes the same degree of recovery (G, I) that the M—N medium promotes (A). If these compounds are added immediately following ex-

posure to ultra-violet no recovery is observed (H, J). Chloramphenicol, added immediately, prevents the recovery promoted by 6-aza uridine (K) and conversely the addition of 6-aza uridine immediately prevents the recovery promoted by chloramphenicol (L). The evidence suggests that ribonucleic acid and protein synthesis during the initial period of incubation following exposure to ultra-violet is requisite to recovery, but is detrimental to recovery afterwards. Recovery apparently requires (1) synthesis of ribonucleic acid and protein in preparation of the deoxyribonucleic acid synthetic system and (2) the prevention of inactivation through unbalanced cytoplasmic growth during the subsequent period required for resumption of synthesis of deoxyribonucleic acid.

Further details of the investigation will be published later. This project was supported in part by a contract with the U S Atomic Energy Commission, AT (40-1)-2139

High Molecular Weight Ribonucleic Acids from the Nuclei of Calf Thymus

A RIBONUCLEIC acid fraction, which gives the characteristic sedimentation pattern shown in Fig 1, has been isolated very recently from tobacco leaves¹, mouse brain² and microsomes of rat liver¹. The molecular weights of components A and B are 1.7×10^6 and 0.6×10^6 , respectively. Although the study has yet to be extended to other systems, I suggested two years ago that ribonucleic acids with molecular weights of about 1.7×10^6 exist in the cytoplasm of many types of cells³. The question that naturally arises is whether ribonucleic acids of such a molecular weight also exist in a nucleus. So far no investigation along this line has been reported. The results presented below appear to provide an answer to the question.

A preparation of nuclei was obtained from calf thymus according to Alfrey and Mirsky's modification of the procedure described by Schneider and Petermann⁴. The nuclei in such a preparation have been shown to be capable of incorporating amino-acids into their proteins⁴. With the aid of Feulgen staining, the present preparation was found to contain three intact cells and sixteen cytoplasmic strands per 360 nuclei. A purified fraction of ribonucleic acids of high molecular weights was prepared from this nuclei preparation according to a procedure that will be published elsewhere⁵. The yield was 0.18 per cent

of the dry nuclei, or 13 per cent of total nucleus ribonucleic acid. (The dry nuclei contained 1.4 per cent ribonucleic acid.) As the nuclei preparation was contaminated with only 5 per cent of cytoplasm and the same procedure produces purified ribonucleic acids of high molecular weights from mouse brain at a yield of only about 20 per cent that of total brain ribonucleic acids, it is concluded that the contamination of the nucleic acid preparation from nuclei with the cytoplasmic ribonucleic acid is slight. This preparation contained less than 0.03 gm. of deoxyribonucleic acid per 100 gm. of ribonucleic acid, as estimated by diphenylamine reaction⁴ and orcinol reaction⁵, respectively. It had the same ultra violet absorption spectrum as the ribonucleic acid preparation from mouse brain.⁶

As indicated by the representative sedimentation diagram in Fig. 2, this preparation of nucleic acids from nuclei contained two major components (a and b) in the same ratio as that found for components A and B in whole tissue or cytoplasm (of Fig. 1). Moreover, the molecular weights of components a and b were found to be the same as those of components A and B, respectively.

Fig. 1. Sedimentation diagram of a purified ribonucleic acid preparation from mouse brain. A solution of 0.17 per cent nucleic acid in 0.02 M phosphate, pH 7.3, was centrifuged in a single-sector cell at 8° C.

One point of difference has been observed between the ribonucleic acid preparation from whole brain and that from thymus nuclei. When a fresh preparation from the brain at a concentration of 2.5 mgm./ml was maintained in 0.02 M sodium phosphate, pH 7.3, for 3 hr. at 3° C, it showed no detectable change in its sedimentation behaviour. If the preparation was made from brain infected with Semliki Forest virus, even its infectivity was preserved. On the other hand, when the preparation from nuclei was

Fig. 2. Sedimentation diagram of a purified ribonucleic acid preparation from thymus nuclei. A solution of 0.25 per cent nucleic acid in 0.02 M phosphate, pH 7.3, was centrifuged in a double-sector cell at 8° C.

subjected to the same treatment, degradation occurred, single and polydisperse sedimentation boundary having a molecular weight of about 0.2×10^6 at the peak of the schlieren pattern was observed. No significant further change resulted from subsequent incubation of the preparation at a concentration of 1 mgm./ml. in 0.01 M phosphate for 15 min. at 83° C. This difference is tentatively attributed to the possibility that the preparation from nuclei was contaminated to a greater extent with some material possessing degrading activity than was the preparation from brain.

The presence of ribonucleic acids of high molecular weights in nuclei as well as in cytoplasm has several important implications. For example, these ribonucleic acids may be the templates for protein synthesis in both nuclei and cytoplasm.

I am indebted to Miss H. J. Scherer for her technical assistance.

Post-Exposure Analysis of Organic Compounds in the Blood by a Rapid Infra-Red Technique

THERE has long been a need for a rapid standard method for the determination of levels of circulating organic compounds foreign to the blood stream. The inability to measure efficiently the blood and urine levels of compounds handled in industrial processes has hindered toxicological research and made adequate control of the working environment more difficult. The physician when establishing a diagnosis of an acute or chronic poisoning from an industrial chemical has had no ready procedure by which to identify the specific compound or to determine its concentration in the blood stream. The infra-red method to be presented satisfies the above implied criteria for an efficient analytical procedure—simplicity, rapidity, sensitivity, and availability.

10 ml of oxalated blood are pipetted into a bacteriological culture tube with an aluminium-lined screw cap. 15 ml of carbon bisulphide, methylene chloride, or other suitable extracting solvent is added, and the tube gently agitated by end-over-end inversion for 5 min. The tube is then centrifuged for 10 min at 500*g*. In centrifuging carbon bisulphide mixtures a refrigerated chamber is used to minimize the explosion hazard. The solvent layer is transferred to a standard infra-red sample cell and its spectrum scanned from 2–16 μ . Cells of 1 mm, 3 mm, or 16 mm thickness are used depending on the sensitivity desired. Occasionally it is advantageous to compensate solvent absorptions by placing a matching cell with pure solvent in the reference beam of the spectrometer. While an improved optical null infra-red spectrometer¹ was used in this experiment, any standard infra-red spectrometer would have served as well.

Table 1 SOLVENT EXTRACTIONS OF BLOOD STANDARDS

* By radioactive count
† Added.

The efficiency of this method for the extraction of a given compound from blood is determined by adding a measured amount of the chemical to the blood and extracting it as outlined above. Organic compounds which are not readily soluble in the blood, such as trichloroethylene and benzene, must be checked carefully when standards are prepared, to ensure that

the exact amount of chemical in solution in the blood is known before extraction. Compounds labelled with carbon-14 are employed for preparation of standards when the solubility in blood is known to be low.

This method has proved satisfactory for the measurement of many commonly employed compounds, including carbon tetrachloride, tetrachloroethylene, and 1,1,1-trichloroethane. Four organic compounds, two of which are not readily soluble in blood, are presented as examples.

Table 1 shows the results obtained upon standardization of the method while Table 2 presents the values obtained after exposure of rabbits to these chemicals.

Table 2

| Rabbit | Exposure | Time after exposure (min) | Solvent | Amount extracted p p m | Calculated blood level p p m (wt/vol)* |

* The blood levels were calculated by multiplying the amount of chemical extracted, by the efficiency of extraction determined from the values presented in Table 1.

This infra-red method for measuring post-exposure blood levels of organic compounds has many advantageous features. It is a simple, rapid procedure which can be performed in any laboratory with infra-red facilities. Although the efficiency with which different organic compounds may be extracted varies considerably, depending on both the solvent and the compound, the results indicate that the efficiency is approximately constant for any particular system. Sensitivities approaching a part per million can usually be attained by the proper choice of solvent. In addition, unknown organic compounds may be identified, more than one compound may be measured with one extraction, and metabolites, such as acetone following isopropanol ingestion, may be found.

The method has also been applied successfully to the analysis of urine, and should be applicable to other biological fluids as well. Work is in progress to deter-

mine more exactly the efficiency of this extraction method for the above and other organic compounds.

We wish to thank Dr Norman Wright for suggesting this approach, and B. H. Blake for obtaining the infra red spectra.

Localization of Haemocyanin on Starch Gel Electrophoretic Patterns

Using the Smithies technique¹ of zone electrophoresis in starch gel Woods *et al.*² have recently demonstrated the occurrence of several haemocyanin proteins in the blood sera of certain crustacean species. The identification is tentatively based on the occurrence of two or more protein bands of a similar order of mobility and which are extremely concentrated in comparison to the other blood protein components.

The finding by Woods *et al.*² of what are assumed to be several haemocyanins in certain species can be interpreted in the following ways: (1) as separate molecular forms of haemocyanin, or (2) dissociation association products or other derivatives of a single molecular form, or (3) one or more non haemocyanin proteins with physical properties similar to haemocyanin but which separate from it during gel electrophoresis. Woods *et al.*² favour, at least in part, the second interpretation of the several constituent haemocyanins. They further suggest that a non copper-containing moiety may have been isolated from other components of a possible haemocyanin polymer of higher molecular weight. In order to test the possibilities that either an intact non haemocyanin molecule which would not contain copper or a haemocyanin fragment devoid of copper may have been isolated electrophoretically, the following experiment was devised.

Crayfish serum was resolved electrophoretically in starch gel using the method of Smithies¹. The crayfish used in this study were of two species, *Orconectes viridis* (Hagen) and *Orconectes propinquus propinquus* (Girard) (kindly identified by Prof. Horton H. Hobbs, jun. of the University of Virginia). Gels were prepared with 12.5 gm of reagent soluble starch (Merk and Co. Ltd, Montreal, Canada)/100 ml of borate buffer (0.02 M boric acid and 0.008 M sodium hydroxide/litre). This gave gels of pH 8.03. The bridge buffer used consisted of 0.20 M boric acid and 0.04 M sodium hydroxide/litre. Electrophoresis was carried out at room temperature for 12 hr at a potential gradient of 0 v./cm. On completion of electrophoresis the gels were sectioned horizontally; one half was stained for protein with amido black 10B dye and the other half was placed for 24 hr in a solution consisting of 50 ml of 10 per cent aqueous sodium acetate and 3 ml of alcohol 0.1 per cent rubranic acid (dithioximide). Gomori³ cites the development of a greenish black colour in this reagent as a histochemical test for copper.

The two *Orconectes* species used gave patterns similar to *Cambarus limosus* (= *Orconectes limosus* (Raf.)) which had been found previously³ to have two haemocyanin bands. Both haemocyanin bands of *Orconectes* stained a light greenish black in the copper reagent. As a control the larval haemolymph protein pattern of the eastern tent caterpillar *Malacosoma americanum* (Fab.) was subjected to the same test. *Malacosoma* has a very concentrated protein component of about the same electrophoretic mobility as the crustacean haemocyanins. However, *Malacosoma* pattern components did not react with the reagent up to 48 hr. Serum of the horseshoe crab *Limulus polyphemus* (L.) (obtained through the courtesy of Dr R. J. DeFalso of the Serological Museum of Rutgers University), which has an extremely concentrated fast migrating haemocyanin component, was also tested in this way. The concentrated component reacted positively with the copper reagent. These observations are summarized in Fig. 1.

Fig. 1. Starch gel electrophoresis diagrams of the blood protein patterns of (A) *Orconectes* spp., (B) *Malacosoma americanum* larvae and (C) *Limulus polyphemus*. The anodic area is to the right of the point of sample insertion (indicated by arrow) and the cathodic area is to the left. The letter H indicates copper containing components.

This experiment does not support the possibility in *Orconectes* of the electrophoretic isolation of a non haemocyanin protein from copper-containing haemocyanin. If there is a dissociation phenomenon involved as suggested by Woods *et al.*² then copper is being distributed between more than one dissociation product.

In connexion with this test yet another possibility arises. The enzyme tyrosinase also contains copper as a co-factor. This enzyme could be present as a separate electrophoretic component or absorbed to another protein. However, *M. americanum* did contain a large amount of tyrosinase in its blood as evidenced by a rapid melanization in the absence of phenylthiourea as an inhibitor. Since copper was not found to be associated with any of the *Malacosoma* protein fractions we can probably rule out tyrosinase as a factor in these *Orconectes* experiments, where there was no appreciable darkening reaction in *Orconectes* blood.

The copper test used here provides an aid to identifying and localizing haemocyanin on invertebrate blood protein patterns. It offers another demonstration^{4,5} of the unique opportunities available

close as possible to the muscle. The photocell is protected from the 366 m μ radiation by a Wratten W-2 filter or by a combination of this filter with a Bausch and Lomb interference filter transmitting a 15 m μ band peaking at 450 m μ . Both filter combinations gave satisfactory results. The photocurrent was amplified by high gain chopper amplifiers and recorded by a galvanometer oscillograph. A 'bucking-out' circuit was used and the increment of fluorescence caused by electrical stimulation is recorded. The scale of the ordinate is given by independent spectrophotometric measurements (Fig. 1).

Fig. 1. Fluorescence response of frog sartorius muscle to electrical contraction at 4 (left) and 1.5 (right) second intervals. The right-hand record indicates a 'saturating' effect. Independent spectrophotometric studies give the concentration scale for the ordinate: this saturating effect corresponds to the oxidation of 0.035 μ moles/gm reduced pyridine nucleotide (ref. 8).

The excised frog's sartorius muscle was contained in a holder where oxygenated Ringer flowed freely past the exposed portion of the muscle^{3,7}. The muscle and the bathing fluid were cooled to 8°.

Fig. 1 illustrates two responses of the fluorescence of the sartorius muscle to a series of twitches. Electrical stimulation is applied every 4 sec in one case and every 1.5 sec in the other case. The twitch of the muscle is indicated as the small and abrupt deflexion on the trace which marks the moment of contraction. There is a decrease of fluorescence in a staircase fashion for the lower stimulation rate. At the higher stimulation rate the fluorescence change reaches a plateau, beyond which further stimulation causes little change. A comparison of these results with those obtained spectrophotometrically⁸ suggests that the same phenomenon is being recorded in both cases: the oxidation of reduced pyridine nucleotide caused by increased adenosine diphosphate concentration at the mitochondria. If we then accept the similarities of the kinetics as sufficient basis to identify the fluorescence decreases changes with the oxidation of intramitochondrial reduced pyridine nucleotide, we can make the following statement: (1) The concentration of adenosine diphosphate arriving at the mitochondria following a single twitch is a small fraction of that required for half-maximal activation of spectroscopic effects in isolated mitochondria (0.056 μ moles/

gm^{2,3}). (2) The staircase response for the 4 sec twitches emphasizes that the low concentration of adenosine diphosphate per twitch applies not only to the first twitch but also the second and possibly later twitches of the frog sartorius muscle.

This method has much to recommend it in terms of simplicity and sensitivity. In addition it may have the further advantages of (a) being applicable to a thick layer of muscle and (b) being relatively insensitive to haemoglobin. It may therefore be much more readily applicable to intact tissues than the spectrophotometric method.

Frequencies of the Haptoglobin Groups in 406 French Blood Donors

The method of zone electrophoresis in starch gel enabled Smithies¹ to describe three haptoglobin groups in human sera. Using a standard technique previously reported^{2,3} we have examined the sera of 406 blood donors living in Paris. In each 'Plexiglas' tray (internal dimensions 234 mm \times 80 mm \times 6 mm) three serum samples mixed with a haemoglobin solution (0.05 ml of a solution containing 50 mgm of haemoglobin being added to 1 ml of serum) were allowed to migrate simultaneously, side by side, for 18 hr, under a potential of 100 V. After electrophoresis the starch gels were divided into two slices and stained, one with amido black, and the other with benzidine reagent for peroxidase activity. The technique was the same as that previously described and used to detect haemoglobins in agar gels⁴ but without using zinc acetate as a solution.

The haptoglobin groups were quite easily identified (Figs. 1 and 2). Particularly the difference between Hp 1-2 and Hp 2-2 was clear-cut: their electrophoretic patterns are very different and it will be seen that the haptoglobin-haemoglobin complex moves more slowly in group 2-2 than in group 1-2.

Fig. 1

Fig 2

The frequencies of the three groups are in agreement ($\chi^2=0.505$ for 1 degree of freedom) with the genetical theory proposed by Smithies and Ford Walker* (Table 1). The gene frequencies are $Hp^1=0.4015$, and $Hp^2=0.5985$. These figures are not significantly different from those already reported, in populations of European origin by some workers, particularly from the important series of Galatius Jensen in Denmark. No mention is made in Table 1 of the results collected in a British and in a Basque sample by Allison *et al.*⁴, who found a fourth haploglobin group (0-0) and whose British series differs significantly from the expected frequencies calculated from the simple two alleles theory. We shall not discuss the interesting finding of the 0-0 group not the cause of the discrepancy: presumably it is attributable to differences in technique.

Table 1

| Authors | Total (N) | Haploglobin groups | | | | | |
|--|-----------|--------------------|--------------|-----|--------------|-----|--------------|

| Present survey (France) | 408 | 62 | 15.27 | 202 | 49.75 | 142 | 34.98 |

* Quoted from Sutton *et al.* who pooled the figures given by Smithies with their own.

† The percentage only was given in the original paper.

If we use only comparable figures, it seems reasonable to consider, from the results of Sutton *et al.*, Smithies, Galatius-Jensen, Laurell and Grubb, Fleischer and Lundvall, and from our own results, that in most of the populations living in the

occidental and septentrional part of Europe and in the white population of America, the frequencies of the genes Hp^1 and Hp^2 do not differ appreciably from 40 to 60 per cent respectively. We agree, however, that the complete system may be much more complicated.

RADIO BIOLOGY

Increased Oxygen Consumption in Rats during Irradiation

METABOLIC changes arising during irradiation are of great importance for understanding the mechanism of the effects of radiation. In work on such changes in rats we have used the estimation of oxygen consumption as a general indicator of the metabolic state.

We used 40 rats (Wistar strain) females, average weight 190 gm. oxygen consumption was measured during irradiation at a dose rate of 50 r/min in every animal separately. The measurements were carried out in boxes 8 cm \times 8 cm \times 10 cm. The amount of air passing the box was regulated in accordance with the body weight of the experimental animal and was determined by the following formula. Amount of air (cm³/in⁻¹) = weight of animal (g) \times 2.5. The procedure was as follows. The animals were kept in the box for 50 min. During the first 20 min they became adapted to the experimental conditions. In the period 20-50 min oxygen consumption was measured. The oxygen consumption between the 20th and 30th minute was taken as the basic value (100 per cent). During the period 30-50 min the rats were subjected to total body irradiation (180 kV, 15 m.amp, 1 aluminium, 0.5 copper, focal distance 40 cm, dose rate 50 r/min.)

The oxygen consumption of control animals was measured under the same conditions but without irradiation, and they were exposed to the noise caused by opening the lead diaphragm of the X-ray tube. This noise had no influence on the oxygen consumption of control animals.

The comparison of oxygen consumption of experimental and control animals is given in Fig 1.

At the time of decreasing oxygen consumption in control rats, that of irradiated rats rises. Increased consumption of oxygen takes place during the first

Fig 1 Comparison of the changes in oxygen consumption of control (---) and irradiated (—) rats. Standard error level is given by vertical lines

minute (50 r), at the fourth minute it reaches the maximum (200 r) and in the tenth minute it approaches the values before irradiation, but is still higher than in control animals

The difference in oxygen consumption in twenty irradiated and twenty control animals during the period from the first to the eighth minute of irradiation is statistically significant ($P > 0.01$)

We have found in the literature two reports on changes in respiratory metabolism during irradiation. In both cases the oxygen consumption was increased at higher doses of radiation than those we have used. In the first case, the rate of oxygen consumption was raised after a dose of 1,000 r in monkeys. In the second case, oxygen consumption of rats and mice was increased during irradiation with a dose-rate of 100 r/min. Our results are in accord with these, significant changes were found after the relatively low dose of 50 r

Prophylactic Effects of Amine Oxides in Radiation Injury in Mice

In 1957, Haley *et al.*¹ found that quinoxaline-1,4-di-N-oxide reduced X-radiation mortality in mice by 50 per cent. Two mechanisms were involved, reduction of bacteremia¹ and interaction with X-ray-produced oxidizing radicals². Comparisons have been made of other N-oxides (Table 1) using groups of 20 CF-1 mice and the same radiation conditions as before¹. The 250 mgm/kg oral dose of drugs was given 24 hr prior to irradiation with 550 r. The two quinoxaline derivatives significantly increased the ST_{50} day but had less effect on total survival than quinoxaline-1,4-di-N-oxide. Erythromycin N-oxide significantly reduced the ST_{50} day and total survival while its anhydro derivative was equivalent to quinoxaline-1,4-di-N-oxide as a radiation prophylactic. All the above compounds are readily absorbed,

Table 1 ORALLY ADMINISTERED AMINE OXIDES AND SURVIVAL AFTER X-IRRADIATION

| Treatment | ST_{50} * and range Days | Slope and range | Total mortality | |
|--|----------------------------|------------------|-----------------|-----|
| | | | Per cent | Day |
| Saline control | 9.4 (8.4-10.5) | 1.29 (1.19-1.40) | 100 | 14 |
| 2,3-Dimethyl-quinoxaline-1,4-di-N-oxide | 12.4 (10.1-15.2) | 1.56 (1.32-1.84) | 85 | 30 |

| Saline control | 12.3 (10.0-14.3) | 1.41 (1.26-1.56) | 90 | 30 |
| Erythromycin N-oxide | 10.0 (9.0-11.2) | 1.20 (1.10-1.40) | 100 | 18 |
| Anhydroerythromycin N-oxide | — | — | 45 | 30 |

* ST_{50} , day upon which 50 per cent of animals are expected to be still alive. Confidence limits are calculated at $P = 0.05$ (ref. 3). All drugs 250 mgm/kg orally 24 hr pre irradiation

excreted slowly in the urine and exert antibiotic effects so the radiation bacteremia could be reduced. On the other hand not all of them can interact with equal facility with the radiation-produced oxidizing radicals. Examination of the chemical structures involved indicated that an amine oxide either in an unsaturated ring, for example, quinoxaline or within one carbon atom of a double bond, for example, anhydroerythromycin is necessary if oxidizing radicals are to be prevented from exerting their deleterious effects. In the dimethyl substituted quinoxalino compounds difficulties in oxidizing the methyl groups are probably the reason for the decrease in protectant activity even though Francis *et al.*⁴ showed that hydroxylation in the 2 position occurs *in vivo*. With erythromycin N-oxide, the double bond is lacking and the compound can be oxidized only with difficulty even *in vitro*⁵. Thus, it would appear that amine oxides with the above chemical structures can reduce mortality from ionizing radiation when administered orally 24 hr prior to exposure.

We wish to thank Imperial Chemical Industries, Ltd., for the quinoxaline compounds and Lilly Research Laboratories for the erythromycin compounds. This work is based on work performed under Contract No. AT (04-1)-GEN-12 between the Atomic Energy Commission and the University of California at Los Angeles.

PATHOLOGY

Formation of the Toxoid of Histamine Sensitizing Factor in *Bordetella pertussis*

It has been reported that mice injected with *Bordetella pertussis* vaccine become exceedingly sensitive to histamine.¹ Maitland *et al.*² found that antibacterial rabbit sera against *Bordetella pertussis* contain antibodies to histamine sensitizing factor. However, it seems that no biological definition of histamine sensitizing factor has been established. We believe that it is a toxin different from the accepted *pertussis* toxin. The present communication deals with formation of the toxoid of histamine sensitizing factor in *Bordetella pertussis* with the use of formalin.

The supernatant of a culture of *Bordetella pertussis*, strain 18-323, was prepared by a method already described.³ Formalin was added to the supernatant to give a concentration of 0.5 per cent. After various intervals of incubation at 37°C, the degrees of detoxification of the histamine sensitizing factor were examined. Tests of the antigenicity of the toxoid thus formed were also carried out.

0.5 ml of culture supernatant to which formalin had been added was injected intraperitoneally into dd mice, weighing about 20 gm each. Five days later the sensitivity to histamine of an inoculated group of mice was tested to determine the degree of detoxification. The mice surviving the histamine sensitivity test were inoculated 14 days later with either *pertussis* vaccine or culture supernatant in order to determine whether they were immune. Five days later their sensitivity to histamine was retested (Table 1).

Table 1 DETOXIFICATION OF HISTAMINE SENSITIZING FACTOR IN CULTURE SUPERNATANT AND ACTIVE IMMUNIZATION OF MICE WITH TOXOID OF HISTAMINE SENSITIZING FACTOR

| Incubation period of formalized culture supernatant at 37°C | Detoxification (loss of histamine sensitizing ability) | Immunization with toxoid against histamine sensitizing factor |
|---|--|---|
| 4 days | incomplete | no immunity |
| 7 days | complete | complete immunity |
| 10 days | complete | no immunity |
| 16 days | complete | no immunity |
| Control: Culture supernatant heated at 56°C for 30 min | no detoxification | no immunity |

As shown in Table 1, the culture supernatant heated at 56°C and containing histamine sensitizing factor without *pertussis* exotoxin activity, afforded the mice no immunity against histamine sensitizing factor. The antigen, when detoxified incompletely or incubated for a prolonged period (perhaps due to partial denaturation) gave the mice no immunity against histamine sensitizing factor, whereas a single injection of complete toxoid established complete immunity against it. Repeated administrations of an incompletely detoxified antigen gave no immunity. However, repeated injections of antigen after prolonged incubation afforded partial immunological protection. These findings suggest that even the presence of a small fraction of histamine sensitizing factor in *pertussis* antigens interferes with the establishment of immunity against it. The incubation period required for the formation of the complete

toxoid is subject to variation according to the preparation used.

The incubation period necessary for formation of toxoid of vaccine, in general, seems shorter than that of culture supernatant. It was estimated to be about 24 hr at 37°C. Formation of the toxoid did not occur following the addition of phenol or merthiolate to the antigen. The heating of the antigen at 80°C for 30 min. resulted in complete inactivation of histamine sensitizing factor and destruction of the antigenicity.

24 hr after intraperitoneal injection of 0.5 ml of freshly isolated sera of rabbit immunized with the toxoid, the mice received intraperitoneal injections of 0.5 ml (15×10^{10} organisms) of *pertussis* vaccine (killed by heating at 56°C) to test for the possible production of antibodies against histamine sensitizing factor. Five days later histamine sensitization was examined. One LD50 for a control group without immune serum was 29.8 mgm/kgm of histamine, while the LD50 for one group of passively immunized mice was more than 480 mgm/kgm, affording good evidence for the presence of antibodies against histamine sensitizing factor.

Rabbit immune sera were able to prevent a reduction in histamine inactivation of a homogenate of the organs of *pertussis* sensitized mice⁴ when the sera were inoculated 24 hr before administration of *pertussis* vaccine.

Thus, it seems reasonable to regard histamine sensitizing factor as a toxin, which apparently has nothing to do with preventive antigen(s).⁵

Immunologically it was demonstrated on rabbit sera immune against the toxoid of histamine sensitizing factor that the histamine sensitization due to *pertussis* vaccine has nothing to do with anaphylactic shock against horse serum.

Maitland *et al.*² and Stronk and Pittman⁶ reported that guinea pigs show no increase in susceptibility after the administration of *pertussis* vaccine. Nevertheless we found a marked reduction in histaminase activity of a homogenate of organs from *pertussis* sensitized guinea pigs using Kapeller Ador's method.⁷ No reduction was observed in the histamine inactivation of a homogenate where guinea pig ileum was employed following an extraction of histamine by a modified version of McIntire's method.⁸ However, at an early stage (first 2-3 hr) of the reaction between the homogenate and histamine, a marked reduction in histamine inactivation was observed when guinea pig ileum was used. The explanation of histamine sensitization in mice and rats, must await further studies, although a reduced activity in histaminase or histamine inactivation may account for a large part of the sensitization to histamine.

For the production of *pertussis* vaccine the existence of histamine sensitizing factor in *pertussis* antigens should not be neglected, because evidence for the existence of antibodies against histamine sensitizing factor in a human hyper immune serum was recently reported by Maitland and Guernli.⁹

Effect of Chlorpromazine on Crocker Sarcoma and Ehrlich Ascites Carcinoma

Goldin *et al.*¹ and Humpreys *et al.*² have stated that reserpine treatment in mice bearing transplanted leukaemia L 1210 caused regression of neoplasm and prolonged the survival time of these animals. These observations have directed attention to other tranquillizers as possible anticarcinogenic drugs. The growth of sarcoma 37 was inhibited by chlorpromazine treatment.³ However, according to Cranston⁴ some tranquillizers belonging to the phenothiazine group did not show any inhibitory effects on mammary adenocarcinomas in mice.

In our Department we have carried out some experiments dealing with the effects of chlorpromazine on Crocker sarcoma and Ehrlich ascites carcinoma in mice.

R III, *B_N* (an inbred strain from our own animal colony) and Swiss mice of both sexes were used. The initial weight of mice was 25–30 gm. Chlorpromazine ('Largactil'—Société Parisienne d'Expansion Chimique S.A., Specia) was given daily intraperitoneally at a dose of 2.5 mgm/kgm body-weight in about 0.25 ml physiological saline. A control group was given saline alone.

The rate of growth of Crocker sarcomas was measured by the mean diameter of the tumours, and that of Ehrlich ascites carcinomas by daily weighings of the mice and by noting their survival times.

The growth of Crocker sarcomas in chlorpromazine-treated and control mice is shown in Fig. 1. Chlorpromazine seems to have no inhibitory effect on this neoplasm—the tumours grew at the same rate as in the control group, despite the depressive effect of chlorpromazine on mice.

Chlorpromazine did not prolong the survival time in R III mice bearing Ehrlich ascites carcinoma (Table 1). However, the gain in weight of these mice was much smaller than that in control mice. The diminished gain in weight was due to the smaller gain in carcass weight, as well as to smaller production of ascites fluid. Analogous results were obtained with Swiss mice (Table 1).

Thus chlorpromazine had no inhibitory effect on the growth of either tumour despite the depressive

action of the drug. The daily dose administered by us was much smaller than that given by Belkin and Hardy³. We found that a single dose of 10 mgm/kgm. that is, five times smaller than that used by Belkin and Hardy, caused a high mortality among the animals.

The technical assistance of Miss I. Juzwa and Mrs K. Chorazy is acknowledged.

Inhibition of Tumour Growth with 2,5-Dicarboxy-3,4-Dihydroxy-Thiophene

The possibility of preferential inhibition of tumour growth by antimetabolites of hexose monophosphate pathway intermediates was suggested by Sahasrabudhe¹. In pursuance of this suggestion it was shown that thiophene-2,5-dicarboxylic acid, administered as its sodium salt, significantly inhibited the growth of transplantable fibrosarcoma in mice and also increased the survival of Yoshida (ascites) sarcoma bearing rats². It was further shown that since this sodium salt is soluble in water, it was probably excreted rapidly. When the total daily dose of thiophene-2,5-dicarboxylic acid was increased and the injection schedule evenly spaced during the day to maintain adequate drug concentration, it was found that the inhibitory effects were significantly enhanced. It was therefore felt that if the free carboxy groups of the acid were esterified to reduce its solubility in water, the drug concentration might remain steady in the system for longer periods. In addition to this if two hydroxy groups are introduced at the third and fourth positions of the thiophene-2,5-dicarboxylic acid molecule, it was thought that the resemblance between the sugar intermediates of the

hexose monophosphate pathway and the antimetabolite would be increased and the effectivity against cancer might also increase. With these objectives in view 2,5-dicarboxy-3,4-dihydroxy thiophene (hereafter referred as 'Dicetol') was synthesized³. Dicetol is insoluble in water and therefore it was converted into a water soluble disodio-dicetol by treatment with ethanolic sodium ethoxide to facilitate its administration in aqueous medium. Disodio-dicetol readily hydrolyses in the presence of carbon dioxide. It was therefore felt that the water soluble compound used for practical reasons, would be transformed in the body into an insoluble dicetol which would probably be retained in the system for longer periods. The present communication reports the results of preliminary screening trials with disodio-dicetol.

Fig. 1 Inhibition of growth of transplantable fibrosarcoma with disodio-dicetol. Top row (C) tumours from control group. Weight of tumours in this group are from left to right: 4.14, 3.61, 5.47, 4.56 and 4.33 gm. respectively. Bottom row (E) shows tumours from treated group. Weights of tumours in treated group from left to right are 1.12, 0.40, 0.92, 0.10 and 0.11 gm. respectively. Treatment was started on the eighth day after transplantation and continued for 15 days. Dose: 150 mgm/kgm body weight/day of disodio-dicetol.

Six to eight weeks-old Swiss mice weighing 20-25 gm were used. The transplantable fibrosarcoma used in the present investigation was originally obtained by Waravdekar and Ranadive⁴ from animals treated with 0.12 dimethylbenzo (1,2,5,4) dithionaphthalene. This has since been maintained in Swiss mice through several serial transplantations. Freshly dissected tumours were chopped to fine pieces and a homogeneous suspension made in normal saline. 0.5 ml of the tumour suspension was injected subcutaneously in each of the animals and the tumours allowed to grow for 8 days. Animals having uniform tumour sizes (visual observation) were divided into two groups. In the experimental group each of the animals received subcutaneous injections of disodio-dicetol in normal saline (1 mgm/0.5 ml) at 0900, 1600 and 2100 hr every day (total daily dose 3 mgm/animal). The corresponding control group received 0.5 ml normal saline only at the times mentioned. Injections were continued for 15 days. The animals were then killed and the weights and dimensions of the tumours determined. Fig. 1 shows the tumours from the control and treated groups placed side by side. The weights of individual tumours are indicated in the legend. The weights of tumours from the control group varied from 3.6 to

5.4 gm, whereas those from the treated group ranged from 0.12 to 1.12 gm. Thus there was significant inhibition of tumour growth in treated animals. Apart from the general reduction in the weights of the tumours in the treated group, there was evidence of regression in tumour size in some animals as can be seen from E4 and E5 in Fig. 1. Further, it is of interest to note that with the doses employed in the present investigation (3 mgm/day/animal, that is, 150 mgm/kgm body-weight/day for 15 days) there were no apparent signs of toxicity in the treated animals. Further work is in progress, details of which will be reported elsewhere.

Appearance of Granules in the Cytoplasm of Tumour-Cell Cultures in Contact with Lysozyme

We have tried to establish whether or not lysozyme added in appropriate concentrations to human tumour cell cultures can produce some morphological changes in such cells. The following human tumour cells were utilized: strain Af (H Ep 2) of epithelial nature and strain A (H S 1) of mesenchymal origin. These strains were kindly supplied by Dr. A. Fjelde, State Serum Institute, Copenhagen.

Gey's liquid medium, without addition of antibiotics, was used in roller tubes. The colonies were treated two or four days after culturing and after growth had been found to be normal. At this point the liquid medium in the tube was replaced by another containing lysozyme chloride in the following dilutions: 0.1, 1, 2.5, and 5 mgm/ml medium. The control tubes contained normal Gey's medium, without lysozyme.

The tumour colonies were tested after 20-min, 1-hr, 5-hr, 10-hr, 24-hr, 48-hr and 6-days contact with the medium containing lysozyme. Slides for microscopic examination were prepared from these cells. Smears were made by using a thin rectangular strip of blotting paper, the cell colony being made to adhere to one end, the blotting paper was then gently passed over the slide, so producing a smear. After drying, the smears were fixed and stained with May-Grünwald's and Giemsa's stains.

Many azurophil granules of various sizes (approximately 1 μ diam.) were observed in the protoplasm of numerous cells from the Af (carcinoma) and A (sarcoma) colonies treated with 2.5 and 5 mgm/ml of lysozyme chloride. These granules became evident, even if small and not very clearly distin-

Fig. 1 Photomicrograph of human cancer cell (Af) treated with lysozyme: the cytoplasmic granules are visible ($\times 300$)

Fig. 2 Photomicrograph of human sarcoma cells (A) treated with lysozyme: the cytoplasmic granules are visible ($\times 300$)

guishable, after 20-min contact with lysozyme, becoming more obvious and reaching the largest size after 48 hr. or more.

The HeLa strain cultivated in Hanks medium, in stationary cultures, gave the same results. The above-mentioned type of granular formations were not observed in the controls.

Other tests were performed on fibroblasts from chick embryos, human kidney cells and monkey kidney cells cultivated both in Gey's and Hanks medium and in roller or stationary tubes. Granules did not appear in the fibroblasts, but were, in contrast, seen in human and monkey kidney cells. However, they appeared much later (after 24 hr.) than in tumour cells, and their number was much lower.

Another test was performed on cells taken from the ascitic fluid of a patient with cancer of the peritoneum. The cells were seeded in Gey's medium, following the roller tube method, and the lysozyme added immediately. The granules were very numerous in the tumour cells but absent from the cytoplasm of the lymphocytic type cells present in the liquid.

The following tests were performed in order to determine the chemical nature of the granules.

(1) *Lipids* Negative results of tests with sudan III, sudan black and Nile blue sulphate. Observation of the granules in polarized light did not reveal birefractive images.

(2) *Nucleic acid* Feulgen's nucleic reaction and the ribonuclease digestion test gave negative results. The granules displayed a certain degree of acidophilia after ribonuclease treatment.

(3) *Polysaccharide* Periodic acid and fuchsin sulphurous acid treatment (Hotchkiss's test) indicates absence of detectable polysaccharides in the granules.

(4) On phase contrast microscopy the granules appear dark, with regular outline and various diameters. They occupy the cytoplasmic portion of the cell, leaving the zone occupied by the nucleus quite free. They also display poor Brownian movement.

(5) On vital staining with brilliant cresyl blue the granules all stain blue, and none become yellow. The granules are partially and weakly stained with Nile blue, there is no tendency to metachromatic staining.

(6) Toluidine blue tests reveal that the granules have a strongly metachromatic character (acidophilia).

Various hypotheses can be formulated with regard to the nature of granules.

(a) They might indicate cellular suffering caused by possible toxic action on the part of lysozyme. (b) Lysozyme treatment may reveal pre-existing formations in the cytoplasm. For example, it might be considered that the basic lysozyme cytoplasm links up with certain protein acids in the cytoplasm. (c) Particular differentiated structures in the cytoplasm such as mitochondrial or ergoplasmic formation may be revealed.

BIOLOGY

Transport of Driftwood from South America to Tasmania and Macquarie Island

IN February 1955 a log about 10 ft long and 5 ft in girth was found washed up on a sandy beach just inside Port Davey harbour on Tasmania's south-west coast. It was lying between two logs of Huon Pine (*Dacrydium franklinii* Hook f.) an endemic conifer of Tasmania. Unlike those logs which were well covered with marine growth it was free from such growth although the surface was 'woolly' with many pebbles embedded in it. The ends of the log were sawn and one end grooved for towing by a wire rope. The wood was identified from its anatomy as a species of *Nothofagus*, which genus is represented in Tasmania, the south-eastern portion of the Australian mainland, New Zealand, New Guinea, New Caledonia and South America. Anatomically the genus can be divided into two easily distinguishable groups, the one covering the species of New Guinea and New Caledonia and the other the remaining species. The log in question was derived from the second of these two groups and, because of the presence of spiral thickenings in the vessel elements, its specific identity could be narrowed down to one of three possibilities, namely, *N. moorei* (F. Muell.) Krasser of northern New South Wales and south-eastern Queensland, *N. pumilio* (Poepp. and Endl.) Krasser and *N. obliqua* (Mirb.) Oerst. from South America. The spiral thickenings in *N. moorei* differ from those of the two South American

species: those of the unknown resembled the thick enings observed in the South American species. Both *N. pumilio* and *N. obliqua* are restricted to South America: the former occurring from Tierra del Fuego north to latitude 30° S on the western side of the Andes; *N. pumilio* *N. antarctica* (Forst.) Oerst. and *N. betuloides* (Mirb.) Oerst. are logged commercially in the southernmost tip of the continent. All the anatomical evidence thus pointed to a South American origin of the log in question although this conclusion met with some initial opposition.

We have found no reports in the literature of driftwood travelling over such long distances (10 000 miles). Cockayne mentions in passing that logs are carried from New Zealand to the Chatham Islands, a distance of 500 miles. Matthews states that the fjords of the west coast of South Georgia contain large quantities of driftwood much of it from wrecks but some consisting of 'the trunks and limbs of several trees one with root stumps at the butt'. Matthews concludes they must have drifted from where they grew 'for no one would have brought such crooked, useless timber across the ocean'. The nearest source would be Tierra del Fuego, about 1 000 miles away. The Australian National Antarctic Research Expeditions to Macquarie and Heard Islands have also reported gnarled driftwood on the beaches of these islands which, like South Georgia, are devoid of native trees.

A request for samples of driftwood from Macquarie Island brought twenty specimens collected by the 1957 party on the west coast and one from a large log on the south coast collected by the 1958 party. All have been identified anatomically. The original twenty consisted of twelve hardwoods, seven softwoods, and one piece of bamboo. All the hardwoods were identified as belonging to the genus *Nothofagus* and seven of these had the well marked spiral thickenings in the vessels characteristic of the South American species *N. pumilio* and *N. obliqua*, other anatomical evidence pointed to *N. pumilio*. The specimen from the large log, collected by the 1958 party, was also identified as probably *N. pumilio*. Only one log was sawn at both ends; the others had no saw or mill marks. The notes accompanying the specimens and the photographs supplied indicated that the logs varied in length from 1 ft to 15 ft and from 4 in. to 30 in. in diameter. One (Fig. 1) was a split boomerang shaped piece and another had root bases protruding at one end. Of the five specimens without spiral thickenings the notes record

Fig. 1. Boomerang-shaped piece of driftwood from the west coast of Macquarie Island identified as *Nothofagus pumilio*. This appears to have been derived from a large limb. The piece was 4 ft long 6 in. tapering to 4 in. in diameter. (Aided by H. MacKay.)

that two of the logs were sawn and that the other logs ranging from 5 to 10 ft in length and from 2½ to 7 in in diameter were not sawn.

There seems little doubt that this collection of specimens has been transported by ocean currents. It would seem most unlikely that some of the pieces had been taken on board ship, even as firewood, although the sawn logs could conceivably have been transported by ship. Eight of the logs were derived from species growing naturally only in South America, 10,000 miles from Macquarie Island, and there is little, if any, commercial traffic in these species outside Chile and Tierra del Fuego. The other five could also have originated from South America. The set of currents in the 'roaring forties' makes their origin from Tasmania or New Zealand most unlikely.

Of the seven softwoods five were identified as spruce (*Picea* spp.) a genus restricted to the northern hemisphere north of latitude 36° and, as far as we are aware, not planted on a large scale in the southern hemisphere. The logs were straight and varied in length from 5 to 15 ft and in diameter from 2 to 10 in. Three had sawn ends, the largest and smallest were not sawn. It is possible that these logs were transported by a ship which was wrecked in southern latitudes but the variation in diameter makes this less likely. Large quantities of spruce are harvested and transported by water down the rivers on both the Pacific and Atlantic coasts of Canada and the Northern United States. Many must escape. Whether some combination of ocean currents would transport them to Macquarie Island must be left for future investigation. However, it is of interest to note that Heyerdahl⁷ has reported the preference of the Hawaiians in the past for drift logs of Douglas fir (*Pseudotsuga menziesii* (Murb.) Franco) for the construction of their ancient canoes.

The remaining two conifers were of the genus *Pinus*, both were derived from logs 9 in in diameter. One was identified as belonging to the southern pine group (for example, *Pinus taeda* L., *P. palustris* Mill., etc.) the other to the white pine group (for example, *P. monticola* Dougl., *P. strobus* L., etc.). The natural distribution of this genus is restricted to the northern hemisphere but many species are widely planted in Australia, New Zealand and Chile. However, representatives of the above two groups are not the ones most commonly used. Thus the chances of these two conifer specimens having their origin in the southern hemisphere are remote.

This small collection of driftwood thus has a most varied geographical origin. There seems little reason to doubt that the *Nothofagus* specimens have drifted from Tierra del Fuego (longitude 70° W) to Macquarie Island (longitude 160° E) and the west coast of Tasmania (longitude 146° E) in the track of westerly winds. Sverdrup *et al.*⁸ give the speed of the surface current in the Antarctic circumpolar drift as 15 cm/sec. Using this figure, the time taken for a log to drift from South America to Macquarie Island would be over 3 years. This represents a maximum estimate of the time for the voyage, since, if any part of the log projects from the water, it will be 'sailed' through the water by the westerly winds. However, it is interesting to mention that a message bottle dropped about 1,250 miles to the west of Macquarie Island was recovered from the beach of that island 10 weeks later, giving a surface speed of, at least, 33 cm/sec.

It is strange that all the hardwoods found and

examined have proved to be *Nothofagus*. This may be an accident of sampling but is due, more probably, to the fact that in the extreme southern latitudes of South America *Nothofagus* forms almost pure stands. It is hoped to obtain further samples of driftwood from Atlantic and Pacific Islands in southern latitudes. In this connexion it is of interest to record that two such specimens have already been received from Tristan da Cunha (12° W) in the south Atlantic and both have been identified as *N. ? pumilio*.

Determinations of air-dry density on various samples of *Nothofagus pumilio* have given values around 32–35 lb/cu ft. In this respect, therefore, they are little heavier than most of the conifers including species of *Pinus* and *Picea*.

The bearing of these results on the problem of the floristic botany of the southern continents will be discussed elsewhere. However, it does not seem impossible for seeds to be overgrown in the wood or, as Darwin observed⁹, trapped and sealed into the interstices of the roots and then transported from one continent to another. This remote chance which has presumably been available for the 100 million years since the origin of the Angiosperms may be part of the explanation of the puzzling floral similarities of the southern tips of the continents.

We wish to acknowledge the help provided in collecting specimens by the officers of the Australian National Antarctic Research Expeditions, in particular Mr. Harry Black, Officer-in-Charge of the 1957 party at Macquarie Island, and by Mr. D. H. Simpson, Agricultural and Forestry Superintendent, Tristan da Cunha. We also wish to thank Mr. W. L. Davies of the Geography Department, University of Tasmania, for his help in discussing these problems of geography.

Sterility in *Lathyrus odoratus* L.

MALE sterility in *Lathyrus odoratus* L. was first recorded by Bateson, Saunders and Punnett¹. Male sterility was absolute and was inherited as a single recessive gene linked to light axil and cretin². Fabergé³ and Upcott⁴ reported that the sterility resulted from disturbances in the meiotic division following normal metaphase pairing. Such plants were normal and fully fertile on the female side.

Table 1

| | No of crosses or selfs | Pods with seed | Total seed | Mean seed per pod | Mean seed per pollination |
|--|------------------------|----------------|------------|-------------------|---------------------------|
| Controlled self pollinations | | | | | |
| (a) Fertile plants | 54 | 29 | 127 | 4.4 | 2.3 |
| (b) Sterile plants | 50 | 0 | 0 | 0 | 0 |
| Crosses between fertile and sterile plants | | | | | |
| (a) Fertile \times σ | 52 | 10 | 22 | 2.2 | 0.42 |
| (b) Sterile \times σ | 50 | 0 | 0 | 0 | 0 |

during prophase (Fig 1), metaphase was characterized by complete asynapsis (Fig 2). The chromosomes

Sterility affecting both male and female gametes has recently been observed in an unnamed blue flecked variety of the sweet pea. (Seed of this variety was supplied by Mr D G Taylor of the Cheshire School of Agriculture.) The anthers contained a small amount of stainable pollen (5 per cent) which rendered them partially fertile as male parents. Table I shows the results of self and cross pollinating fertile and 'sterile' plants. From many hundreds of flowers on the 'sterile' plants, one pod set (from an uncontrolled pollination) containing two seeds. Hence sterility was almost complete on the female side and high on the male side. Cytological observations of the meiotic division in the pollen mother cells showed that although normal pairing occurred

during the first division remained undivided and were randomly distributed into two or more groups. Each group of chromosomes behaved normally for the completion of the meiotic division, though seldom was a viable gamete produced, as few of the first division segregations were genomically reductional. The cytological behaviour of this asynaptic form of *L. odoratus* closely resembled the observations reported by Blakeslee *et al*³ for the asynaptic variant of *Datura*.

Segregation ratios from heterozygous material suggest that this asynaptic sterility is controlled by a single recessive gene.

Tolerance to Skin Homografts of Adult Mice after Parabiosis

Skin grafts between mice of different inbred strains are invariably rejected within a few weeks. Hybrid (F_1) tissues transplanted to mice of either parental strain are also consistently rejected at the same rate if the parents differ at the $H 2$ histocompatibility locus¹. This uniform incompatibility was not apparent when such hybrids were united in parabiosis with parental strain inbred mice. The most frequent result of such unions was the death of only the hybrid partner, usually within a month. Hybrid death in this period was characteristically preceded by a severe wasting disease sometimes described as parabiotic intoxication².

The variability of survival time of the parabiotic unions between different strain combinations is shown in Table 1. The F_1 hybrids were all crosses between inbred mice of different $H 2$ genotypes. All animals were of the same sex and 2-3 months old when united. The parabioses that persisted beyond 60 days were eventually terminated by the 'natural' death of both partners without manifestations of the wasting disease.

Of the combinations tried here, the parabiosis of the ($CSH \times DBA/2$) F_1 hybrids with $DBA/2$ inbred mice

Table 1. SURVIVAL TIME OF PARABIOTIC UNIONS BETWEEN INBRED STRAINS OF MICE AND THEIR F_1 HYBRIDS OF THE SAME SEX AND AGE (2-3 MONTHS)

| Combination in parabiosis | No of pairs done | Pairs survived beyond 60 days | Death of hybrids Time in days | |
|--|------------------|-------------------------------|-------------------------------|-------|
| | | | Average | Range |
| ($CSH \times DBA/2$) F_1 — $DBA/2$ | 71 | 29 | 19.7 | 13-31 |
| ($B6/129 \times DBA/2$) F_1 — $B6/129$ | 6 | 0 | 14.8 | 12-16 |
| ($B6/129 \times C57BL$) F_1 — $B6/129$ | 8 | 1 | 16.1 | 14-21 |
| ($C57BL \times C57BL$) F_1 — $C57BL$ | 15 | 0 | 26.1 | 8-57 |
| ($C57BL \times C57BL$) F_1 — $C57BL$ | 17 | 0 | 20.2 | 9-31 |
| ($DBA/2 \times DBA/2$) F_1 — $DBA/2$ | 4 | 1 | 23.0 | 14-33 |

Fig. 1. Metaphase showing chromosome pairing as evidenced by (1) small impaired region, A and (2) probable inversion loop B. ($\times 1,500$)

Fig. 2. Metaphase I showing 14 unpaired chromosomes. ($\times 1,500$)

provided the most frequent stable unions. Fourteen such pairs that were not treated further survived in stable parabiosis for periods lasting 80–510 days. The two successful parabioses among other strain combinations in Table 1 survived 310 and 85 days.

Parabiotic pairs that had been together for about five months were used for the first skin grafting experiment (Table 2, Group 1). The full thickness skin of young ($C3H \times DBA/2$) F_1 hybrids were grafted to each of the five $DBA/2$ mice still in parabiosis. The grafts were all successful. Three months later the skin of inbred $C3H$ mice was placed adjacent to the earlier grafts. These were also uniformly successful, in spite of the major histo-incompatibility between the two inbred strains. Approximately two months later (10 months after parabiosis) all of the unions were surgically terminated. The host $DBA/2$ mice survived up to six months after the termination of parabiosis with all the grafts still in place. In the next experiment (Table 2, Group 2), 3 $DBA/2$ mice in parabiosis for 5 months were grafted only with $C3H$ skin. As soon as the skin was well established, the parabionts were cut apart. After another 2–3 months the grafts began to contract slowly, disappearing 3–4 months after the termination of parabiosis.

Table 2. RESULTS OF GRAFTING $C3H$ AND ($C3H \times DBA/2$) F_1 SKIN ON $DBA/2$ MICE AFTER PARABIOSIS WITH ($C3H \times DBA/2$) F_1 HYBRIDS OF THE SAME SEX AND AGE (2–3 MONTHS)

| Group | No of mice | Days after parabiosis at which indicated events occurred | | | | |
|-------|------------|--|----------------------|--|---------|-----------|
| | | Experimental | | | Results | |
| | | Skin graft while in parabiosis | Parabionts separated | Skin grafts ($C3H$) after separation | Slough | Dead |
| 1 | 5 | $\left\{ \begin{array}{l} 162-165 \\ (F_1) \\ 224-228 \\ (C3H) \end{array} \right\}$ | 307 | none | no | 418–488 |
| 2 | 3 | $\left\{ \begin{array}{l} 120-130 \\ (C3H) \end{array} \right\}$ | 176 | none | 298–317 | no (>400) |
| 3 | 1 | none | 306 | 401 | no | 446 |
| 4 | 2 | none | 154 | 209 | no | no (>270) |
| 5 | 2 | none | 82 | 98 | 144–171 | no (>270) |

In the following three groups (Table 2, Group 3–5), the $C3H$ skin was successfully grafted on $DBA/2$ mice after the parabiosis with the hybrid had already been terminated. In one instance an initial $C3H$ skin graft was accepted three months after separation of the parabionts. However, when the total period of parabiosis was just 82 days, compatibility lasted for only 2–3 months after the surgical parting. In other cases, where parabiosis had been allowed to persist for 5 months, the subsequent period of compatibility is continuing after 4 months.

It should be pointed out that in no case has a graft of $C3H$ or ($C3H \times DBA/2$) F_1 skin on untreated $DBA/2$ control mice shown comparable compatibility. More than 100 such control animals always rejected these homologous skin grafts within 3 weeks and never showed the full regrowth of hair that was characteristic of the good acceptance of $C3H$ skin in the parabiosed $DBA/2$ mice.

When ($C3H \times DBA/2$) F_1 hybrids died by the wasting disease during the early weeks after the parabiosis,

the surviving $DBA/2$ partners were tested for their reaction to grafts of $C3H$ skin. In these cases, the outcome was a typical 'second set' reaction, the rapid and violent rejection of the foreign skin. Evidently antibodies were already present when the skin homograft was presented. Other recent evidence^{3–4} indicates that the 'wasting disease' syndrome, as seen in the hybrid, is the consequence of an immunological reaction of parental strain lymphoid elements against hybrid tissues. The reverse cannot occur, the hybrid does not produce antibodies to parental strain tissue. Therefore, as expected, the wasting disease was never seen in the parental strain in parabiosis with its hybrid.

The present observations may perhaps be interpreted in the context of other studies^{5,6}, where the injection of blood and minced tissues create 'enhancement' of transplantation, rather than immune rejection. The deciding factor in these experiments seems to be the quantity of antigen and the mode of injection. While small inocula given subcutaneously provide immunity and rejection, large amounts given intravenously may do the opposite—promote tolerance. In this light, the rejection of homografted skin may be considered the result of a small antigenic stimulus by the graft itself, while the occurrence of successful parabiosis is always preceded by the continuous intravenous exchange of large amounts of antigen. Only after such successful parabiosis was tolerance to homotransplantation demonstrable.

This investigation was supported by a research grant, C-2750, from the National Cancer Institute of the United States Public Health Service.

Common Attractant for the Tobacco Hornworm, *Protoparce sexta* (Johan) and the Colorado Potato Beetle, *Leptinotarsa decemlineata* (Say)

THE specificities of oligophagous insects to groups of related plants have been postulated and demonstrated in several instances to be mediated by secondary plant substances of limited distribution (reviewed by Dethier¹ and Fraenkel^{2,3}). These substances are variously called attractants, taken stimuli, or phagostimulants when they serve in such capacity and are generally tested on the feeding stages of the insects concerned by applying the substances on various artifices such as filter paper, pith disks, non-host leaves or agar gel diets. The insects are then allowed to discriminate the presence of the attractants by biting or feeding.

The function of specific substances in the feeding

behaviour of the Colorado potato beetle *Leptinotarsa decemlineata* (Say) has recently been a centre of interest in many laboratories, especially in France Germany, and the U.S.S.R. (see, for example the report of the symposium on "Insect and Foodplant" held at Wageningen¹). While most of the relevant work deals with the identity and function of glyco alkaloids in Solanaceae as factors of repellency or toxicity, the nature of the specific attractant has commanded little attention. Hesse and Moier² claimed acetaldehyde as the specific attractant, but this claim was not substantiated by later workers. Earlier, Chauvin³ reported the isolation from potato leaves of an attractive substance which was tentatively identified as a flavono glycoside. The technique was improved later⁴ and the attractiveness of the substance was confirmed by Thorsteinson⁵. During an investigation of the oligophagous habits of the tobacco hornworm, *Protoparce sexta* (Johan), which also feeds on members of the same family of plants Solanaceae, a glycosidic substance attractive to this insect was isolated from several plants including tomato and potato⁶. We had an opportunity to assay this material on filter paper against the Colorado potato beetle and found that the material was also highly attractive as a feeding stimulant for the beetle (Fig. 1).

Fig. 1. Biting responses to the attractant purified from tomato leaves by the Colorado potato beetle (left) and the tobacco hornworm (right). A and C on the filter paper are control spots on which 0.01 M of sucrose was applied. B represents test spots on which a solution of the attractant was applied.

The chemical identity of this substance has not been elucidated as yet, but preliminary characterizations indicate that it is not a flavonoid derivative. In our experiments flavonoids were removed before subsequent purification and hence the flavono glycoside claimed by Chauvin as the active substance for the Colorado potato beetle might have been present in his preparation as an impurity. The results of our bioassay strongly suggest that the specific attractant for the potato beetle and tobacco hornworm is identical.

GENETICS

Simultaneous Change in Both Differential and Interference Distances of Chiasmata

On the basis of a serial formation of chiasmata in time beginning from the centromere the effect of experimental factors on chiasma formation has been interpreted in terms of the two parameters differential and interference distances¹⁻³. By differential distance is meant the distance of the first chiasma from the centromere, and by interference distance the length of the chromosome arm between the successive chiasmata. With a change in the differential distance alone the graph showing the relation between chromosome length (x) and chiasma frequency (y) has a series of parallel lines for different temperatures, intersecting the line $y = 1$ at their respective differential distances (Fig. 1a). Mather² interprets Whitt's results⁴ from temperature experiments as showing this type of effect. On the other hand, if only the interference distance changed, the different lines would radiate from the same point (Fig. 1b). Mather² again explains the data of Moffatt⁵ on different individuals of *Culex* as representing this type of change. Apart from these examples by Mather which have become classical in studies on chiasma frequency there does not seem to have been any other interpretation of results along such lines. Data was therefore extracted from experiments of mine^{6,7} which had shown that temperature reduced chiasma frequency per pollen mother-cell in the bluebell, *Endymion nesciutus* (L.) Garek.

Fig. 1. (a) Graphical representation of chiasma frequency-chromosome length relationship when there is a change in differential distance only. (b) Graphical representation of chiasma frequency-chromosome length relationship when there is a change in interference distance only.

The data for the present study came from three clones (C_1 , C_2 , A_{11}) two of which consisted of two individuals each and the third one of three individuals.

The two plants of each of clones C_1 and C_2 were placed at temperatures of 10° and 25°C., and the three plants of clone A_{11} at 0°, 10° and 25°C. It is not possible to give the full results here; they will

Fig. 2 Regression lines for relation between chromosome length (long arms of the complement) and chiasma frequency at 10° and 25° C (in clone C_6) in the bluebell, *Endymion nonscriptus*

be published elsewhere. They consisted of the mean chiasma frequency of each bivalent as well as its component arms in each of the plants under study (see also ref. 6). The present studies were confined to the long arms of the chromosome complement since they could each form more than one chiasma.

The graphs showing the relation between chromosome length in microns (x) and chiasma frequency (y) for each plant at a particular temperature were constructed from corresponding calculated regression lines between (x) and (y) as described below.

Clone C_6 . At 10° C the regression coefficient b was 0.1264 which was highly significant, $F = 20.5869$ ($P < 0.001$), at 25° C, b was 0.07276, also significant, $F = 18.3367$ ($P < 0.001$). The calculated regression lines are shown in Fig. 2. The two lines are clearly separated from each other and they have different slopes. They would be expected to be parallel if there was only a change in differential distance.

Clone C_8 . At 10° C the regression coefficient b was 0.13601 which was highly significant, $F = 17.37465$ ($P < 0.001$), at 25° C, b was 0.11058, also highly significant, $F = 22.6005$ ($P < 0.001$). The calculated regression lines are similar to those for clone C_6 in showing not only a change of position but also of slope. In fact, they seem to combine parallel and 'radiating' lines at the same time as one would expect with a change in both differential and interference distances.

Clone A_{18} . This clone with three plants was examined for this relationship at 0°, 10° and 25° C. The regression coefficient was significant ($P < 0.001$) at each temperature (at 0° C, $b = 0.11297$, $F = 25.4306$, at 10° C, $b = 0.11489$, $F = 36.5462$, at 25° C, $b = 0.11175$, $F = 76.1858$). The calculated regression lines show a much smaller change in slope than those for clones C_6 and C_8 , but the change is still clear. This could be inferred from the similarity in the regression coefficients at the three temperatures in clone A_{18} , and is probably also due to the relatively smaller decrease in chiasma frequency in this clone between the temperatures 10° and 25° C as compared with those in clones C_6 and C_8 . Thus it seems that in clones C_6 and C_8 , and A_{18} , both the differential and the interference distances have been altered by temperature.

Further examination was made of the long arms of the long chromosomes. Since there seems to be a better correlation between chromosome length and

chiasma frequency of the long chromosomes in a varied chromosome complement than of the shorter ones², the long arms of chromosomes A , B , C and D , which could each form up to three chiasmata, were used directly in plotting a relationship between their lengths in microns and chiasma frequency at 10° and 25° C. From these it is clear that the same sort of relationship of the two lines is obtained by this direct plotting, that is, the lines show clearly not only a change of position but also of slope.

The present results suggest a simultaneous change in both the differential and interference distances with changing temperature. A case of this joint change does not seem to have been predicted or reported. The examples given by Mather³ deal only with an independent change in either parameter.

Anomalous Genetic Interactions observed in *Bacillus subtilis*

GENETIC transformation in *B. subtilis* has recently been reported by Spizizen¹, but as yet no paper has appeared discussing genetic interaction between the cells of spore-bearing bacteria. In this communication, a new fact will be described which was discovered while attempting to cross auxotrophic mutants of *B. subtilis* K. It involves the *de novo* appearance of characters not present in the parent strains. The complete details of this work will be published elsewhere.

Two mutants were employed: $T16$ —try, ade, str-r (requiring tryptophan and adenine, and streptomycin-resistant), and $M12$ —met, his, str-s (requiring methionine and histidine, and streptomycin-sensitive). These biochemical mutants were obtained after exposure to X-rays, and the streptomycin-resistant strain was obtained by Szybalski's agar-gradient method.

The mutants were cultivated in nutrient broth at 30° C until the cell density reached about 10^8 /ml. Centrifuged cells were washed once with phosphate buffer and the cell suspensions were plated in mixture on synthetic media supplemented with various nutrients (see Table 1). After four days at 37° C a considerable number of tiny colonies appeared on the supplemented media, but nothing appeared on the minimal medium. In general, the tiny colonies were analysed by spreading cell suspensions prepared by homogenizing the colonies in a small blender on various media.

Table 1 FREQUENCIES OF TINY COLONIES

| No. of cells plated | No. of tiny colonies appearing on | | | |
|--|-----------------------------------|----------------------|----------------------|----|
| | THS | TMS | MHS | MM |
| 716×10^7 + 312 1.0×10^7 | 14 | 8 | 44 | 0 |
| Frequencies | 1.6×10^{-7} | 9.1×10^{-8} | 5.0×10^{-7} | — |

Total cell number was determined on nutrient agar. It was impossible to count tiny colonies on MHS and MM on account of the rapid growth of back mutants.

MM: Gray and Tatum's agar medium. THS: MHS plus tryptophan 60 μ M, histidine 60 μ M and streptomycin 100 μ M. MHS: MHS plus methionine 60 μ M, histidine and streptomycin. TMS: MHS plus tryptophan, methionine and streptomycin.

(1) The occurrence of a *met*, *his*, *ura* *str* *r* strain in two tiny colonies which appeared on THS medium were subcultured on the same medium. After 2 days the cells resulting from each tiny colony were analysed. In all cases, both *try* *ade* *str* *r* and *met* *his* *ura*, *str* *r* progeny were obtained (for example one tiny colony consisted of 13×10^7 *try* *ade* *str* *r*, and 0.5×10^8 of *met*, *his*, *ura*, *str* *r*). In another experiment which was repeated from the beginning, the *met* *his* *ura* *str* *r* progeny were again obtained from the cell suspension which was prepared directly from a tiny colony but this time *try*, *str* *r* progeny were recovered instead of *try*, *ade*, *str* *r*. The appearance of the *met*, *his* *ura* *str* *r* type is of particular interest, because the requirement of uracil for growth is a new character which did not exist in the parental strains.

grow on MHS, TA and nutrient agar but not on MH medium. (b) cells grown on TA or nutrient agar yielded no colonies on MHS medium, (c) the morphology of the colonies on nutrient agar with streptomycin was different from that of T16 (Fig 1), and they could grow on MHS but not on TA or TAS media but when one of them was cultivated in nutrient broth supplemented with streptomycin they segregated out *try* *ade* *str* *r* progeny with a frequency of 10^{-2} . (d) no streptomycin sensitive progeny were obtained at all.

These facts (see Fig 2 for summary) indicate that the streptomycin dependent cells when subcultured on MHS medium maintain the potentiality to segregate *try* *ade* *str* *r* progeny. This phenomenon may be explained by the assumption that the streptomycin dependent progeny consisted of single cells which had a whole chromosome of T16 and a fragment of M12 at the same time. But the two genetic units might not fully complement one another.

A similar genetic interaction between two types of genome was reported by Bradley in *Str. colicolor*².

Fig 1 Colonies on nutrient agar with streptomycin

* Phenotypic expression
Fig 2 Progeny of tiny colonies

(2) The occurrence of streptomycin dependent strains One of the tiny colonies on MHS was analysed by spreading a cell suspension on various media. It was found that the colony consisted of a large number of *try* *ade* *str* *r* (335×10^3), and a small number of *try*, *str* *r* cells (133×10^3) nothing was observed on MH medium. Despite the fact that no colonies appeared on MH medium, a considerable number of colonies (153×10^4) did appear on MHS medium. These colonies behaved as follows: (a) the cells

GEOGRAPHY

Evidence of a South Equatorial Countercurrent in the Pacific Ocean

An eastward flowing current of speeds from 10 to 25 cm/sec is indicated along a density surface ($\sigma_t = 26.81$) in the Pacific Ocean south of the equator in a position roughly symmetrical to that of the (North) Equatorial Countercurrent. Along this surface the current is found between lat 2° S and 8° S at long 105° E and progressively farther south toward the east, to between lat 10° S and 14° S at long 95° W. The depth of this surface rises to the south along the flow, from 400 to 300 m in the west and from 400 to 350 m in the east.

The evidence lies in the calculations of geostrophic flow along this surface with respect to 1,000 decibars¹. The eastward geostrophic flow is indicated on ten cross sections made by the *Equapac* expeditions (joint surveys carried out by agencies from France, Japan and the United States) in late summer of 1956, on three sections made by the *Carnegie* cruise of 1929-30 ref 2 and by combinations of stations from the *Carnegie*, *Eastrop*³ and *Downwind* (Univ. of Calif. Scripps Inst. of Oceanogr., unpublished reports) expeditions.

On this surface the path of the eastward flow coincides with a tongue of high salinity extending eastward from a maximum value in the Coral Sea.

North of the equator the (North) Equatorial Countercurrent is indicated on the same density surface by calculations of geostrophic flow. The depth of the surface rises to the north from more than 400 m at the equator to a ridge of depth less than 300 m at lat 6° N long 175° E. The ridge extends eastward to lat 10° N long 145° W at less than 300 m. It continues from there to lat 6° N.

long 115° W, where its depth is about 350 m. The eastward flowing current is evident on this surface between lat 2° N and 5° N in the west, from lat 4° N to 8° N in the central ocean, and from lat 5° to 10° N at long 120° W, and is indicated on all of the *Equapac* sections and the pertinent *Carnegie* and *Eastropic* sections all the way to the coast of America. Direct measurements⁴ made recently in the eastern Pacific have revealed that the eastward flow extends to at least 1,000 m at long 107° W.

There is evidence of an eastward flow at the sea surface south of the equator in the measurements of geostrophic flow made on the *Equapac* expeditions by the research vessels *Orsom III* (Institut Français d'Océanie, New Caledonia, unpublished report) at lat 9° S between long 170° and 180° E, where speeds as high as 15 cm/sec are indicated, and by the *Hugh M. Smith*⁵ at the same latitude between long 169° W and 135° W, with speeds as high as 8 cm/sec indicated. Of the other *Equapac* lines, none reached so far as lat 10° S except one at long 164° by the *Horizon* (Univ of Calif Scripps Inst of Oceanogr, unpublished reports) and this was so near the Solomon Islands that the geostrophic calculations, which did indicate an eastward flow, might have other interpretations.

In a combination of stations from the *Carnegie* expedition and the *Eastropic* expeditions of 1955 and the *Downwind* expedition, a weak easterly flow may be interpreted so far east as long 95° W, but the observations are sparse and the feature is very poorly defined.

In the western Pacific, other evidence for the eastward flow at the sea surface may be found in various atlases prepared from observations of set and drift of vessels. The British average⁶ of set and drift for the seasons November-January and February-April indicate a weak eastward flow at lat 10° S from long 165° E to 140° W and from long 165° E to 165° W, respectively. No evidence is found in other months, and it is to be noted that the *Equapac* observations were made in August. The more recent Netherlands⁷ monthly current charts show easterly flow along lat 10° S from long 165° to 180° E in February, March and April. The American⁸ monthly charts show almost no evidence in any month.

The east-flowing current was encountered while studying the distribution of temperature, salinity, and oxygen along the density surface $\sigma_t 26.81$, which lies in the intermediate water in the North Pacific and above the intermediate water of the South Pacific. This study is not yet completed, and further information about the flow at other depths and along other surfaces will be obtained as the work progresses.

River Flow in Great Britain

PROF D. L. LINTON, in his article on "River Flow in Great Britain, 1955-56"¹, has a map showing 'run-off deficit', defined as "Precipitation minus run-off".

While believing that maps of this parameter are much needed, it is doubtful whether the data from which they can at present be constructed for Great Britain are sufficient for drawing isopleth maps with any degree of accuracy. The network of gauging stations is too thin for it to be possible to assume that known errors in measurement of run-off, and in assessing rainfall over a whole catchment area, can cancel each other out. The estimation of precipitation is likely to be the most unreliable in large catchment areas of high relief, and these areas happen in general to be where the river-gauging network is particularly thin. These errors can alone well account for the apparently anomalous high run-off deficits in the Scottish Highlands without necessarily invoking any other explanation.

Prof Linton comments that the geographical variations of the fractions of precipitation disposed of by run-off and by evapo-transpiration are radically different, and adds "it is doubted whether there has previously been any general appreciation of this difference by water engineers and others". There may not have been a "general appreciation" of this fact, but it has certainly been appreciated by some, who further appreciate that there is an important difference which is not revealed on his map, and which Prof Linton does not mention, between different parts of the country. In fact of course the map, allowing for the errors mentioned above, does indicate the general geographical distribution of actual loss by evapo-transpiration, this however is in some parts of the country equal (in 1955-56, as in other years) to potential evapo-transpiration and in other parts not. In the rainfall year in question, the difference between actual and potential evapo-transpiration can safely be said to have been between 0 and 2 in in many parts of western and highland Britain, while it almost certainly reached 12 in in many parts of the south of England. Thus an 'actual loss' of 20 in in Ross-shire (as shown on the run-off deficit map) would be a 'run-off deficit', with little or no 'water deficit' while a similar run-off deficit in the south of England would be accompanied by a water deficit of 12 in. It needs to be emphasized that 'water deficit' is not the same as 'run-off deficit', but values of both are needed, and there is need for a network of observations sufficient for both to be mapped. Consideration of both would reveal why there can be a high run-off deficit in the west Highlands, without any need to refer, as Prof Linton does, to the large bodies of open water there, there are, after all, large bodies of open water in the English Lake District, which had a much lower run-off deficit on the 1955-56 map.

Although, as Prof Linton points out, there is a lack of gauging stations on the western seaboard, it is possible to extrapolate the map of 'discharge ratio' to the west coast, through observation or estimation of potential evaporation.

RESEARCH ASSOCIATIONS AND THEIR FUNCTIONS

IN its report for the year 1958 the Council for Scientific and Industrial Research discussed briefly its general policy towards the research associations expenditure on which in revenue and capital grants it envisaged as rising by about a third during the next five years, because their scope and activities are growing steadily in response to the expressed needs of industry. The Council's policy, however, is that industry should bear an increasing share of the total operating cost of the associations, and it is envisaged that over the next five years grant-earning income from industry will be 46 per cent greater than during the past five years, while the grants themselves will be only 34 per cent greater. For the year ended March 31, 1958, annual grants to the associations totalled £1,700,330, compared with £1,424,830 in the previous year, with special grants of £32,571, compared with £120,954. The total income of the associations is given as just under £7 million. It was stated that during the fifteen months ended December 31, 1958, new or revised terms of grant had been awarded to ten of these associations.

The new terms are set out in 'Research for Industry, 1958' * (see also p. 238 of this issue). This report on the work of the industrial research associations includes a summary of the report of the Industrial Grants Committee, which at the request of the Council has surveyed the work done by research associations, and the methods used to assess the applications for grants received from industry. The main conclusions and recommendations of this Committee have been accepted by the Council and, besides considering research association grant policy in the period 1957-64 the Committee's report reviews particularly the achievements of the ten associations which have received new or modified terms of grant. "Research for Industry, 1958" also includes an assessment by Dr D. T. A. Townsend of the place of the research associations in the evolution of scientific endeavour in Great Britain, and a report prepared for the Committee of Directors of the Textile Research Associations on how co-operative research serves the textile industries. These two surveys throw rather more light than the new terms of grant on how in practice the Council's new policy is being interpreted.

The Industrial Grants Committee was greatly impressed with the rapid progress of research associations towards maturity and with the rising quality of the research they carry out and the services they give to industry. The Council is satisfied that co-operative research, as fostered by the Department, is of great value to industry and the nation, and that the Department of Scientific and Industrial Research should continue to give it whole-hearted support.

Department of Scientific and Industrial Research. Research for Industry 1958. A Report on Work done by the Industrial Research Associations in the Government Scheme. Pp iv+135. (London H.M.S. Stationery Office 1959.) 7s. 6d. net.

All told, the grant aided organizations in the scheme serve about 55 per cent of British manufacturing industry and besides basic and applied research their activities include the study of factory operations and working conditions, library and information services and technical and advisory work for individual firms. The largest single function is applied research on problems common to the whole of the industry served.

The Council also endorses the Committee's view that co-operative research brings important specific benefits to industry, economizing on money and scientific manpower, and offering a scientific service to firms that cannot afford research departments of their own. It helps to guide industry towards an appreciation of the value of research in general and facilitates an exchange of technical information and other forms of mutual assistance. Finally, it builds up a store of knowledge on which the nation through Government departments can draw.

These are large claims, some of which have been challenged at least to the extent of asking whether certain functions could be more efficiently served in other ways or by changing the technical character of the associations themselves. Nevertheless their acceptance by the Council seems to dispose of any suggestion that the Council is intending to wind up some of the research associations. Indeed it is specifically stated that the expansion contemplated over the next quinquennium allows for an increase in their number, since recent estimates of the Department suggest that nearly a fifth of the net output of British manufacturing industry comes from trades which in the Committee's view are not fully covered by existing research facilities. Some of these trades might in future be appropriately served by grant aided research associations.

Until the Second World War, Government aid to research associations in Britain was based on the assumption that they would eventually support themselves entirely. In 1945, however it was decided that this policy was no longer in the national interest, and that industrial grants should become one of the continuing activities of the Department. The procedure now generally followed is to award a basic 'block grant' and supplement it with an 'incentive' payment which varies (up to a maximum) according to what income an association can raise from its members. Aid is generous to a young research association serving an industry which does not yet recognize the full value of research, but as the association establishes itself and increases both the scale of its work and the contribution science can make to the productivity of its member firms the incentive is gradually reduced, and it ceases altogether when the association reaches its appropriate size.

Even so Dr D. T. A. Townsend points out that eleven associations have an annual income of less

than £50,000 and only two receive more than £500,000. Eighteen have incomes between £50,000 and £100,000, eight between £100,000 and £250,000, and seven between £250,000 and £500,000. These are not high figures for research to day, and it could be asked whether they are always high enough for efficiency. The Industrial Grants Committee is clearly asking the right questions when a grant comes up for review at the end of five years, and the Council accepts its view that it is important to continue paying a block grant after the association has reached an appropriate size.

This size obviously must take account of the adequacy of the facilities of an association for effective research, but the Council concurs in the Committee's view that continuance of the block grant will enable the Department to exercise an important and beneficial influence on industrial research and ensure that each association has the necessary proportion of basic research in its programme. It is also argued that a channel is thus kept open for the steady flow of research results to Government departments, this helps to prevent undesirable overlapping of projects and to secure desirable co-operation on programmes of wide interest.

Before these propositions are accepted, their implications for the Council of Scientific and Industrial Research require examination. They presuppose the existence of an administrative structure for which even the Lord President of the Council has disclaimed responsibility. Some overlapping should certainly be prevented by the Council for Scientific and Industrial Research, but it should be clear from the discussion aroused by recent proposals for a programme of space research to be undertaken by Britain that there is by no means general agreement that administrative arrangements are yet such as to ensure the minimum of overlapping, much less the most desirable balance and distribution of research effort.

Since the policy of reducing incentive grants was adopted in 1951, the overall ratio of grant to industrial income has fallen from 1.165 to 1.25, and the lowest individual ratio is now 1.46. There is nothing mechanical about the trend, and although the ratio is not given for the ten associations for which the terms of grant were revised during the past year, the ratio of incentive grant to additional income varies from 1.1 to 1.2, and the maximum incentive grant from £3,000 to £18,000. These figures show, however, that the reduction of incentive grants is being exercised with the flexibility which the Council adumbrates.

It is recognized that a long time may be required for an association to convince industry of the value of its work and that if the incentive grant is reduced too quickly, industrial research may be discouraged and the purpose of the grant defeated. Likewise, changes in the purchasing power of money have to be considered, particularly when research associations receive only a block grant. An allowance to restore the real value of the grants was made in 1955, and the Industrial Grants Committee recommends a similar provision if necessary for the next quinquennium.

More important than this question of finance, however, is that of function. The Council endorses the Industrial Grants Committee's view that it is very important to keep a proper balance in the activities of the associations between basic research, applied research (including development work) and information, liaison and consultant services. In some industries pioneering studies of factory operations and working conditions are best made on a co-operative basis, and the Council believes that research associations should extend this work where conditions are suitable, and that, wherever appropriate, the Department of Scientific and Industrial Research should carry out its research in this field and disseminate the results, in close collaboration with the associations.

No indication is given as to what is regarded as a proper balance between the various activities. That will naturally vary from industry to industry, as well as with the maturity of the association. It is left for Dr Townend to supply a rough estimate as to the proportion of the £7 million of the total income which is spent on fundamental research, though this estimate does not necessarily also indicate the proportion of man-power which is devoted to fundamental research. Of a total staff of some 5,000, 1,450 are graduates or possess equivalent qualifications, 1,750 are research assistants, 850 artisans and 950 administrative staff.

Both the Council and its Industrial Grants Committee hold that, so long as co-operative research programmes do not suffer, research associations should be encouraged to undertake a reasonable amount of sponsored research. Some associations are already prepared to do so, and generally have a small proportion of their staff engaged in this way. The practice offers definite advantages in giving research workers useful experience and in strengthening the contact between research associations and industry.

The Council insists, nevertheless, that the chief task of the research associations is co-operative research and that there are other facilities for sponsored research, offered by private bodies without Government assistance. It would welcome increased participation by research associations in sponsored research, but such activities must be kept within reasonable limits. In future a grant-aided association is free to undertake sponsored projects without consulting the Industrial Grants Committee provided the income arising is unlikely to exceed 15 per cent of total income in any year, and that the estimated cost of any one project is not more than £5,000.

Dr D. T. A. Townend's review examines this question of function a little further. He points out that the present total income of the research associations in Britain, namely, £7 million, must be compared with the expenditure of private industry on research and development of £58,000,000, or 0.8 per cent of industrial output, and this £7 million is less than half the £14.4 million expended on research undertaken within the universities in science, technology, medicine and agriculture, towards which the Government provided about £12 million. The universities are mainly concerned with extending the frontiers of

scientific knowledge in an atmosphere of intellectual freedom and usually without regard to the immediate and specific applications of their work. Industrial laboratories, he suggests, are mostly devoted to study of the processes and products of a particular firm with the object of developing something which that firm can do and will do, probably to the exclusion of others.

That the last proposition should not be accepted without qualification does not, however, affect the validity of Dr Townend's claim that the research associations are in a unique position to pinpoint the research problems of importance to the whole of their respective industries. The validity of that claim depends rather on the effectiveness of their contact with the industries they serve, their ability to recruit and retain staff of appropriate experience and ability, and on the quality of their directorate. Some of these factors can be influenced by the Council for Scientific and Industrial Research, but only to a limited extent and they should be borne in mind in considering Dr Townend's argument. There is a separate domain between the universities and industry, he argues, in which knowledge of the basic principles of industrial processes has to be sought with a particular and definite objective. This region accordingly is mostly unsuitable for the universities and is also somewhat too long in range or too expensive at least for the smaller industrial firms in their own laboratories. This he claims, is particularly the domain of the research associations, with their resources and teams of scientists capable of covering a variety of disciplines with a character and individuality of their own. There is no fuss about claiming freedom of action—the Industrial Grants Committee is emphatic as to the need for preserving the autonomy of the associations—nor are unattractive features of the field of investigation neglected.

Dr Townend believes that industry in Britain has been well served by the research associations for many years in a well-defined field uniquely appropriate to the associations with no fear of overlap, and he also suggests that the practice in most associations of pursuing both long range and short-range objectives side by side contributes to the long term future of the industries they serve as well as to the vitality of the overall activity of the associations. As to the balance of research, Dr Townend refers to a recent survey of the activities of some thirty two associations, which showed that the proportion of effort devoted to basic research varied from 10 per cent to 67 per cent the average being about 28 per cent, whereas that devoted to applied research averaged 63 per cent. Close contact has almost invariably been established between the associations and the universities wherever research work of relevance to that of the association is already undertaken at universities. Sometimes the associations assist university departments by contracts or by financing fellowships or bursaries, and this assistance may be given to an existing programme in a university department, or an association may seek to arouse the interest of a university department in a new subject.

Dr Townend appears to be satisfied that these arrangements are adequate. They increase the 'thinking potential' of an association and help to relate the work of university scientists to the needs of industry. Often they are particularly effective in ensuring that university workers are provided with a correct translation of an industrial problem into scientific terms and they supplement the necessarily limited results obtained by postgraduate students with ancillary measurements and background information, thus enabling the results of the work to be applied more readily. What is not specifically stressed is the atmosphere for research which the associations could provide and which was rightly stressed by Mr J. Wilson in his Hinchley Memorial Lecture last year, and this atmosphere is one which the Council for Scientific and Industrial Research could certainly foster.

Clearly the interchange of staff between the research associations and the universities can be beneficial here but Dr Townend notes that such transfer has decreased in recent years, possibly in consequence of the general shortage of scientists and of the rapid growth of departments of science and technology within the universities. This interchange could well be as important as the interchange of staff between the associations and industry itself and valuable as may be the contributions of the associations in research, they will only render their full service to industry when such interchange of staff proceeds freely and to the maximum extent. It can be an important factor, as Dr Townend notes, in supplying industry with senior staff at the managerial as well as the technical level, and the educational potential of the associations is not the least reason for justifying the continuance of support from the Department of Scientific and Industrial Research. There may well be scope for further specific development of the training potential of the associations without interfering with their primary and main function of co-operative research. It should be clear however that if they are to render their full contribution to industrial development, they must be assured not only of wise and far-sighted leadership, but also of sustained financial support, probably on a more generous scale than the resources at present available to the Department of Scientific and Industrial Research have yet permitted.

ROCKETS AND SATELLITES

Manual on Rockets and Satellites

Edited by L. V. Berkner, in association with Gilman Reid, John Hancsian, Jr and Leonard Cornier (Annals of the International Geophysical Year, Vol. 6). Pp. xx+508. (London and New York: Pergamon Press, 1958.) 160s.

THERE is little doubt that this volume of the Annals of the International Geophysical Year contains the most comprehensive account yet published of the researches being carried out and the methods and techniques being used in the fields of rockets and satellites. Any book dealing with such

a young and rapidly growing subject will inevitably date rather quickly, and it so happened that the launching of the first Russian Earth satellite occurred at a very late stage in the preparation of this work. The preliminary account of the Russian results, and the rapid switch in the emphasis of the American satellite programme from the *Vanguard* to the *Explorer* series, are dealt with rather briefly in annexes. It is perhaps fortunate that we have on record here, written before it was overtaken by events, the American plan for the scientific programme intended for the *Vanguard* satellites.

Viewed as a whole the volume cannot fail to be an invaluable source of reference to workers in the field. The upper atmosphere research rocket which still has a vital part to play is not neglected, but the greater part of the book is devoted to Earth-satellite programmes and plans. Those whose interest is more general will gain an insight into the complexities of planning and the widespread co-operation needed in a space research programme, in addition to a sober review of the many new avenues of scientific research now being opened. The volume takes the form of a series of scientific papers, covering subjects as diverse as the design of instruments for many rocket- and satellite-borne experiments, and the organization of volunteer visual observing teams, both in the United States and in the U.S.S.R. It is indeed pleasing to find an international flavour throughout, with significant contributions from the U.S.S.R.

The book is handsomely produced and illustrated, as is to be expected for the price. One must hope that the end of the International Geophysical Year itself will not prevent the compilation of further authoritative international volumes in these expanding fields.

MICROCOSM TO MACROCOSM

Matter, Earth and Sky

By Prof George Gamow Pp xi+593 (London Macmillan and Co., Ltd, 1959) 50s net

EXUBERANT and encyclopædic are the only terms to describe this interpretation of the material universe, most appropriately dedicated to "Aspiring Youth". In the days of stone-turning and avenue-exploring, barriers had to be either surmounted or torn down. Prof Gamow himself was the first to realize that with the right kind of approach nothing so drastic is needed, and that they can be gently tunneled through. There is certainly a barrier between the experience of the ordinary individual and the physicist's interpretation of it. In this book, without demanding excessive penetration on the part of the reader, the author has successfully brought into the open the truths that occupy the inner levels of the well.

The style follows the author's usual successful formula—saying what comes naturally. There are some old friends, including C. G. H. Tompkins, translated to an American setting, but still on a communal Cambridge bicycle. The illustrations are excellent, original and relevant—even those that are put in just for fun, like the one showing an 'experiment' on the thermal expansion of a body, which looks rather unkind. Scientists are pictured with a richly human touch—Otto Hahn registering sheer amazement at the fission of uranium, Compton

strumming his banjo with effect, and Bohr in orbit on a motor-cycle.

The book is divided into three sections. The first, on "Matter and Energy", deals with the elementary physics of the surroundings, relating everyday observations to fundamental principles. This ranges widely from simple mechanics to computers and satellites and rocketry and relativity. The second, entitled "Microcosm", starts with the kinetic view of matter in terms of molecules, and covers atomic and nuclear physics, and a good deal besides. The chapter on the chemistry of life, which goes very fully into protein structure, and discusses Watson and Crick's model of the structure of deoxyribonucleic acid and its implications for the possible working of heredity, is important both for its contents and its influence on the young reader who may (though not if he has got so far through the book) tend to regard physics as a little remote from living. The third part, "Macrocosm", deals with the Earth and its history, the planets, the evolution of the stars, the origin of the elements and of the galaxies, and the recent theory of continuous creation.

So much could not have been achieved in a single book without very careful planning of the sequence of material, and much skill has been devoted to placing the discussion of a fundamental topic in relation to the general framework. Electrolysis, for example, appears in the second part, where the electrical nature of matter is treated. This means that it is a book to be read through, without dodging back to the beginning for explanations.

It is a splendid book, and highly to be recommended to the general reader and for the library. Although very good value for money, its price unfortunately places it high up in the gift-book class. The unkind experiment mentioned above supposes the co-operation of a good-natured relative, and any aspiring youth who can get such a one in an expansive mood would be well advised to clamour for this book as a present instead.

G. R. NOAKES

SURVEYS IN 'APPLIED' MATHEMATICS

Some Aspects of Analysis and Probability

By Irving Kaplansky, Marshall Hall, Jr, Edwin Hewitt and Robert Fortet (Surveys in Applied Mathematics, Vol 4) Pp xi+243 (New York John Wiley and Sons, Inc., London Chapman and Hall, Ltd, 1958) 72s net

THIS book is the fourth of John Wiley's "Surveys in Applied Mathematics", its production was sponsored by the United States Office of Naval Research and by the editorial board of "Applied Mechanics Reviews", its authors are described as being, and indeed are, "internationally recognized authorities in the areas of applied mathematics covered by their surveys". Hall writes on combinatorial analysis, and Fortet on probability theory, while functional analysis and abstract harmonic analysis are surveyed respectively by Kaplansky and Hewitt. An English reader, accustomed to the rigid division between applied mathematics (where nothing is proved) and pure mathematics (where nothing is useful) may well find the classification puzzling. Only the probabilist will be untroubled by it, his subject, having an axiomatic foundation and yet deriving

all its inspiration from practical problems, has no place in the traditional classification, he will be quite happy in the applied mathematical club so long as the topological algebraists are there to keep him company.

Kaplansky's article (32 pages) is the shortest in the book, but is supported by a magnificent bibliography of 113 entries, nearly half of them concerning papers by Russian authors, he gives a remarkably clear and concise account of many topics of current interest in the theories of Banach spaces, locally convex spaces and Banach algebras.

Hall's survey of combinatorial analysis will be of value not only to algebraists but also to statisticians interested in the existence and construction of designs and to the industrial mathematician concerned with linear programming. For the latter there is a fascinating chapter on the theorems of Philip Hall, König and Ramsey, and their applications, these include the transportation problem, the travelling salesman problem, and also such curiosities as the following (Erdős and Szekeres, 1935) "There exists an integer valued function $N(n)$ of the integer variable n such that every set of N points in the plane, no three on a line, will contain n points forming a convex n -gon".

Hewitt's long article on abstract harmonic analysis presents a connected account of a difficult and important field, which is the more valuable because a large number of the most important papers reviewed here were published in Russian. Readers of the older text-books on Lebesgue integration encounter theorems of two kinds: those which make essential use of the group structure of the real line, and those which do not. Those which do not (for example, the Lebesgue convergence theorems) properly belong to measure theory, while those which do (for example, theorems about convolutions, and the whole of the Fourier theory) can nearly all be generalized to the situation in which the real line is replaced by a (say, abelian) locally compact group and Lebesgue measure is replaced by Haar measure, and this is the situation with which abstract harmonic analysis is concerned.

Fortet gives a most valuable account of a number of special topics in probability theory, of which the most characteristic is development of techniques for handling random elements of general type. A probability space is a non-vacuous set Ω a Borel field \mathcal{F} of measurable subsets of Ω , and a totally finite measure μ on \mathcal{F} normalized so that $\mu(\Omega) = 1$. A random variable $x(\cdot)$ is a mapping from Ω to the real line such that all counter-images of real intervals are \mathcal{F} -measurable, and an n -dimensional random variable is defined similarly. The classical theory was concerned exclusively with finite sets of such random variables: the modern theory of stochastic processes is concerned with infinite sets of random variables, suitably parametrized, and the theory of general random elements is concerned with (in the first instance single) random variables $x(\cdot)$ where now the range of the mapping $\omega \rightarrow x(\omega)$ lies not on the real line nor in n -dimensional euclidean space, but in some more general topological-algebraic structure. For example, Mourier and Fortet have studied random variables taking values in a Banach space, and Gelfand has studied random (Schwartz) distributions. In a sense the distinction between stochastic processes and general random elements is artificial for if $\omega \rightarrow x(t, \omega)$ (for each t in some parameter set T) is a set of random variables constituting a

stochastic process, then $\omega \rightarrow x(\cdot, \omega)$ can be thought of as a general random element, and conversely most of the general random elements one wishes to consider in practice (random ergo-distributions, random energy-spectra, etc.) can be reduced to systems of numerical random variables. But the direct treatment of a random variable of general type, where possible, offers many attractions, and there can be no doubt that this branch of the subject will attract considerable attention during the next few years.

The publishers are to be congratulated both on the quality of the surveys included in this volume and on their decision to publish this group of four surveys together.

D G KENDALL

FUTURE MARINE BIOLOGICAL RESEARCH

Perspectives in Marine Biology

A Symposium held at Scripps Institution of Oceanography, University of California March 24-April 2, 1958. Edited by A. A. Buzzati Traverso. Pp. xvi+621. (Berkeley and Los Angeles: University of California Press, London: Cambridge University Press, 1958.) 75s. net.

"APPROXIMATELY 90 to 95 per cent of all biologists are engaged in terrestrial biology. These biologists have a tendency to consider Marine Biology as a somewhat secondary biological annex." P. Drach (p. 603 *et seq.*) further states that general biology can never be properly balanced if based predominantly on terrestrial forms, however important they are to our welfare, a view shared by many of the contributors. The expansion of marine biology is reflected by the wide range of subjects presented at a symposium planned to focus attention on forthcoming fields of marine research. It is significant that a number of contributions come from non-marine biologists. Forty-one papers with subsequent discussions, are arranged in four sections: ecology, physiology and biochemistry; behaviour, evolution and genetics.

Ecological papers by P. Drach, L. Zenkevitch, G. Thoren, A. C. Hardy and others, while emphasizing that more field observations on animal communities are required, show the urgent need for new design and international standardization of instruments and techniques for quantitative sampling. Field observation is so much stressed that K. M. Rao's plea, echoed elsewhere for laboratory observation and experiment on marine equivalents to the guinea pig and fruit fly stands out from the rest. D. P. Wilson's studies on the ability of organisms to detect factors at present defy analysis, and so select a particular substrate, are stimulating. Further emphasis on this need for study on microconstituents is given by S. K. Kon (vitamins and external metabolites), D. I. Arnon (micronutrients) and I. Provasoli (growth factors of marine algae). E. Baldwin's paper on biochemical perspectives and the need for more biochemists in marine research is timely.

Papers on reef building corals (C. M. Yonge), productivity, patchiness and succession in plankton (W. Rodhe *et al.*, R. Margalef, A. C. Hardy, L. Tonelli and V. Tonelli), cell chemistry (E. S. G. Barron, A. Szont Györgyi), biological clocks (C. S. Pitten

drigh, F A Brown, jun) show the variety of future problems That the section on behaviour consists of four papers as compared with twelve or thirteen of the other sections emphasizes our lack of knowledge W H Thorpe's excellent discussion of ethology indicates the vast amount of data awaiting discovery by simple observation assisted by aqualung, television and camera, and T H Waterman's contribution on underwater polarization patterns suggests many new ideas about plankton behaviour

If the biochemist is rare in marine biology how much more the geneticist Yet D L Ray shows that many species are suitable for genetical study, while papers by V L Loosanoff and Y Matsui point the way to controlled shellfish breeding and farming Geographical distribution, races, speciation of pelagic forms where there appears to be no barrier to gene flow, are challenging problems to all

This book is not just a list of problems for the future Most contributors base their speculations on accounts of present work, much of it unpublished Many contributions are of immediate concern and it is regretted that it has taken more than two and a half years to produce a book that one might expect—and hope—will soon be out of date Errors are few, the chief being the transposition of legends to text-figures 2 and 12 in Hardy's paper, while the last two lines to the legend of text-figure 1 of Bogorov's paper should read "continuous line indicates quantity of phytoplankton and broken line quantity of zooplankton" That the contributions are contained in 621 pages is largely due to the small type, but it remains easy to read and the tables and figures are well set out Non-marine biologists would do well to read this book for much of it has general biological implications

J A ALLEN

HETEROCYCLIC CHEMISTRY

Heterocyclic Chemistry

An Introduction By Prof Adrien Albert Pp viii+424 (London The Athlone Press, University of London, 1959 Distributed by Constable and Co, Ltd) 45s net

Six-Membered Heterocyclic Nitrogen Compounds with Three Condensed Rings

By C F H Allen, in collaboration with G M Badger, Bruce Graham, G A Reynolds, James H Richmond, John R Thirtle, J A Van Allan and C V Wilson (The Chemistry of Heterocyclic Compounds a Series of Monographs, Vol 12) Pp xxii+624 (New York Interscience Publishers, Inc, London Interscience Publishers, Ltd, 1958) 196s

CHEMISTS in general and students in particular have long been in need of a book of reasonable size on heterocyclic chemistry, but the digestion, selection and presentation of the subject have apparently daunted chemists, for Morton's book, published in New York in 1946, has been the only work of note to appear for many years This is not surprising, for our present detailed knowledge of heterocyclic chemistry must exceed in volume that of aliphatic or of aromatic chemistry, and the infinite variety of heterocyclic compounds must cause this difference to become ever greater A work by Prof Albert is therefore warmly welcome, and it is exceptionally interesting to see how he has approached

the task of giving a concise account of this subject in 375 excellently printed pages

He has certainly broken completely away from the orthodox treatment, in which each class is usually discussed largely in the order syntheses, reactions, and finally structure on the basis of these two sections Instead, Prof Albert makes primarily an electronic structure approach to the various classes, and also discusses their physical properties, particularly spectra, ionization constants, oxidation-reduction potentials, and dipole moments in considerable (and very valuable) detail, relegating much of the synthetic side to smaller print This makes absorbing reading to the more advanced chemist, but one wonders whether students will both grasp and then continue to visualize the main bulk of heterocyclic compounds as "π-Deficient N-Heteroaromatics", "π-Excessive N-Heteroaromatics", and "π-Excessive O- and S-Heteroaromatics", which form the titles of the author's three main chapters?

The author has dealt with the problem of condensing the sheer bulk of material partly by confining references to original literature to papers published since 1930, on the ground that these papers will provide sufficient references to earlier work The result can be unfortunate, for an account of fundamental work is often followed solely by a recent reference, which may record comparatively trivial modifications or extensions of the earlier work consequently the student may often lack the means to honour "the memory of the pioneers of heterocyclic chemistry" to which the book is dedicated It is a pity, furthermore, that although two distinct series of volumes on heterocyclic chemistry are still appearing, references are given almost solely to Eldorfeld's series, and the larger Weissberger series is almost ignored

The reviewer notes with interest the categorical statement that purines synthesized by building a pyrimidine ring on to an iminazole ring "have always introduced a hydroxy- or amino-group in the 6-position" (p 198) Mann and Porter, in 1945, synthesized by this method a number of 1,7-dialkyl-purines which did not contain these groups in this position

The fresh approach, the clear lucidity of the presentation, and the author's personal enthusiasm have produced a book which chemists will read with great interest

The other volume, the twelfth to be published in the Weissberger series, is devoted solely to the chemistry of compounds having three six-membered rings fused together, the only hetero element being one or more nitrogen atoms The vast amount of information, carefully classified and coded in about 600 pages, vividly illustrates the reviewer's earlier comment on the expanse of our knowledge of heterocyclic chemistry The book deals with the chemistry of aza- and polyaza-anthracenes, -phenanthrenes and -benzonaphthenes, the amount of work entailed becomes apparent when one recalls that the monaza-phenanthrenes alone form a group of five isomers Furthermore, tables are provided enumerating all the known simple and substituted members of each class up to 1952 This vast accumulation of knowledge has required the services of several chemists, and it concludes with an excellent chapter on "The Ultraviolet Absorption Spectra of Polycyclic Heterocyclic Aromatic Compounds" by Prof G M Badger, of the University of Adelaide This volume forms an outstandingly valuable addition to the Weissberger series

F G MANN

Puzzle-Math

By Dr George Gamow and Dr Mervin Stern. Pp 110 (London Macmillan and Co, Ltd, 1958) 8s 6d net

BOOKS of the 'mathematics for fun' type are often neither very mathematical nor very funny but those who know some of Dr Gamow's earlier writings will expect this volume, in spite of its catchpenny title, to combine amusement with instruction, and they will not be disappointed. The thirty-three problems are entertainingly set out, and solved by honest mathematical processes, involving little or no manipulative technique. There are some chestnuts—the three travellers with dirty faces, the fly between two approaching trains—but many of the problems are new or not widely known. Is a motorist likely to be held up longer at a level crossing if the track is double than if it is single? When we ring for a lift why does it seem to come in the wrong direction more often than not? A bright student might easily be led to a better appreciation of the fundamental logic of mathematics by reading this cheerful little book. T A A BROADBENT

Transactions of the International Conference on the Use of Solar Energy

The Scientific Basis, held at Tucson, Arizona, U.S.A., October 31 and November 1, 1955 (Sponsored by University of Arizona, Tucson, Arizona Association for Applied Solar Energy, Phoenix, Arizona, Stanford Research Institute, Menlo Park, California) Vol 1 The Available Energy Measurement of Radiation Pp xvi+135 Vol 2 Thermal Processes, Part 1 Section A, Flat Plate Collectors Pp ix+145 Vol 2 Thermal Processes, Part 1, Section B, High Temperature Solar Furnaces Solar Power Pp i+146-204 Vol 3 Thermal Processes Part 2, Solar House Heating Solar Water Heating Solar Stoves Solar Distillation Pp x+168 Vol 4 Photochemical Processes Pp xii+187 Vol 5 Electrical Processes Pp xii+132 (Tucson, Arizona: The University of Arizona Press 1958) 12 50 dollars the set

THESE Transactions containing 85 scientific papers totalling 887 pages, represent one of the most valuable publications on solar energy research. It is therefore all the more regrettable that although the conference at which these papers were presented was held late in 1955 publication has been delayed until the end of 1958, and moreover that there is no record of the valuable discussions that took place at the conference.

The conference discussed the scientific basis of solar energy research and was followed by the World Symposium on Applied Solar Energy at Phoenix, Arizona. The papers at the latter conference which dealt preferentially with applications, were published in 1956, and the proceedings were reviewed by the writer (*Nature*, 178, 229 1956), who also described in some detail the general features of both conferences soon after the meetings (*Nature*, 177, 110 1956).

The present review is therefore restricted to consideration of a few aspects which have since been emphasized as important by the trend of solar energy research in the interval that has elapsed since presentation. Interest in the flat plate type of collector used for water heating continues but research is concentrated on the simplification of design and the use of metallic oxide surface coatings

to restrict re-radiation of long wave length and thus enable higher temperatures to be attained. The high cost of the silicon photo-cell which was then newly developed, has as prophesied been reduced to economic competition with electricity from dry cells and is coming into general use for portable radio and telephone equipment, not excluding such objects as space satellites. The solar furnace sponsored by the French Government and described by M Trombe in Vol 2 is the most active achievement at present and similar furnaces have been sponsored by the governments of other countries for testing materials to resist the thermal shock encountered in high speed rocket flight and space travel.

The Transactions are essential to those embarking on solar energy research, or wishing to ascertain the state of knowledge up to very recently. Although there have been some remarkable developments since the conference, this set of volumes which has been compiled by Prof Carpenter of the University of Arizona Observatory, constitutes a record of permanent value. H HERWOOD

The Fundamentals of Statistical Reasoning

By M H. Quenouille (Griffin's Statistical Monographs and Courses No 3) Pp 169 (London Charles Griffin and Co Ltd, 1958) 34s

A GOOD short book on the basic principles and theory of statistical inference, expository of those parts of the subject on which statisticians are now generally agreed and objectively critical of some of the more controversial lines of thought, would be of great value. Such a book appears to have been Mr Quenouille's aim, but he has had indifferent success. Few subjects are in greater need of careful choice of every word, yet all too often the writing here is ambiguous or lacking in clarity. For example the opening paragraph of a chapter on testing hypotheses tends to obscure the important distinction between decision theory and scientific inference that Fisher and Barnard have so usefully emphasized in recent years. Later in the same chapter 'restriction' of errors of both the first and the second kind is said to be essential to a significance test of (surely "of deviations from" would be clearer) a null hypothesis.

The first four chapters rapidly survey the concepts of probability, elementary distribution theory, estimation and hypothesis testing. The second half of the book is of a different order of difficulty and of much greater interest. Here is an introduction to maximum likelihood and fiducial inference that could well form the basis of a more substantial text and could stimulate further research. Mr Quenouille has a gift for devising the illuminating example. He has evidently devoted much thought to fiducial distributions and one wishes that he would undertake the systematic and critical account of this topic that must supplement Fisher's more intuitive approach if it is to attain its proper recognition. Unfortunately, the present book is again unsatisfying not only because of limitations of space but also because too often the reader cannot tell what is part of standard theory, what is a new contribution from the author (possibly deserving more explanation or more detailed reference to other publications) and what is a tentative suggestion for future exploration. However, although one may question the wisdom of including some of this material in an introductory book, undoubtedly the more advanced student will value it. D J FISHER

The Nature of Experience

By Sir Russell Brain, Bt (The Riddell Memorial Lectures, Thirteenth Series, delivered at King's College in the University of Durham, 12, 13 and 14 May 1958) Pp viii+73 (London Oxford University Press, 1959) 8s 6d net

ACCORDING to the trust deed, the Riddell lecturer is required to discuss "the relation between religion and contemporary development of thought". It is interesting to look back over past titles, and to see how successive speakers have interpreted their task. In this context, how well these discourses—the thirteenth—fit into the series, and maintain their tradition.

The theme is the field of perception, which the author explores with the object of attaining a view sufficiently comprehensive to restrain, if possible, the excessive specialization which is the outstanding characteristic of modern thought. The three lectures are entitled, (1) "Vision and Fantasy", (2) "The Nature of Perception", (3) "Symbol and Image". Some useful notes and references follow at the end.

Sir Russell is a leading neurologist, and one would expect to find a telling picture of mental processes, in the event, this knowledge is linked with rare aesthetic insight.

The first lecture reviews the conventional sense-impressions and their many contrasts with the structure of matter as the physicist knows it. The author believes that the qualities perceived are constructs of our own brains. Of particular interest is the account of abnormal states produced, for example, by mescaline. The second lecture contains a well-balanced review of the objections which have been raised against the writer's theory. In the last lecture, perhaps the most difficult, art is taken "as the embodiment of feelings in perceptual form", and thus embraces that subjective element deep in human nature which raises it, at times, to an image of the Divine.

F I G RAWLINS

Kingdom of the Octopus

The Life-History of the Cephalopoda. By Frank W Lane. Pp xx+287+48 plates (London Jarrolds Publishers (London), Ltd, 1957) 30s net

MR LANE'S book provides a collection of superb photographs for which the amateur naturalist and professional zoologist must be equally grateful. The full bibliography, clearly representing an immense amount of hard work, will be of value to the teuthologist, making available a number of obscure references and enabling him to examine for himself the provenance of the many curious and often entertaining legends and observations embodied in the text, and thus to make his own estimate of their scientific value.

The text has the inevitable failings of one written by an author who has no (and does not claim to have) specialist knowledge of the subject, and for whom it is therefore hard to assess the relative importance of the different facts and concepts which he has collected. Without such evaluation, however, verbally accurate statements can become misleading, and this fault is intensified, in Mr Lane's book, by a tendency to dramatic presentation which results in important aspects of the subject receiving less full treatment than relatively trivial but striking details. A similar weakness is to be found in the references

made to authors in the text. Mr Lane is most careful to quote his sources, but, too often, equal weight is apparently given to the long-established findings of famous zoologists, to isolated observations scarcely yet verified, and even to statements, not necessarily accurate, introduced casually in the writings of specialists on other fields.

These failings will not diminish the interest which the rich anecdotal material and fine illustrations will rouse in the general reader, but, as a result of them, the book is scarcely suitable for the use of the student who seeks accurate and balanced information, and is not a book to be used for professional teaching without constant checking.

ANNA M BIDDER

Die gesunden und die erkrankten Zahngewebe des Menschen und der Wirbeltiere im Polarisationsmikroskop

Theorie, Methodik, Ergebnisse der Optischen Strukturanalyse der Zahnhartsubstanzen samt ihrer Umgebung. Von Prof W J Schmidt und Dr A Keil. Pp 386 (München Carl Hanser Verlag, 1958) 48 DM

THIS book is undoubtedly a classic of its kind by authors who are world authorities in this particular field. It deals in the greatest detail with the normal structure of the calcified tissues of the teeth of man and animals, and then proceeds to a consideration of their structure in disease. The study of the calcified tissues of the teeth has always presented considerable difficulty. The two methods which have been used most are microradiography and polarized light. It seems a pity that no attempt has been made in this book to consider microradiography, but there is no doubt that the use of polarized light as here described and the interpretations given make it a very delicate method for this work. Much difficulty has been caused in the past by faults in interpretation arising from form birefringence and the possibility of birefringence arising from the organic matrices of some of these structures, but these are now all explained in detail, giving a proper scientific basis for further study.

This is the only authoritative work on the subject. It is beautifully produced and very well illustrated. No department, dental or zoological, dealing with the structure of normal or diseased teeth can afford to be without it.

A I DARLING

Hundred Years of the University of Calcutta

Supplement. Pp xviii+732+95 illustrations (Calcutta University of Calcutta, 1957) n p

THE Centenary History of the University of Calcutta was reviewed in these columns a little more than a year ago (*Nature*, 180, 1152, 1957). This massive supplement adds a large volume of material, including descriptive accounts of the 274 colleges which are or have been affiliated with the University, similar accounts of the development and present state of the institutes and departments of the University, a select list of research publications, a list of University and College teachers in 1956, and a record of the speeches and ceremonies with which the centenary was celebrated in January 1957. There are nearly one hundred attractive photographs, chiefly of college buildings. This is the largest University in the Commonwealth—probably in the world—putting itself on record for posterity.

RADIATION MEASUREMENTS TO 658,300 KM WITH PIONEER IV

By PROF JAMES A VAN ALLEN and LOUIS A FRANK

State University of Iowa, Iowa City

Introduction

THE present report comprises (a) the radiation observations obtained with the US deep-space probe *Pioneer IV*, (b) a comparison of these observations with those of *Pioneer III* and of the first Soviet cosmic rocket and (c) an interpretative discussion.

The *Pioneer IV* programme was conducted under the same auspices as those for *Pioneer III*. The radiation detectors and the payload assembly were developed, calibrated and tested co-operatively by the Jet Propulsion Laboratory of the California Institute of Technology and by the State University of Iowa. The four stage rocket vehicle and associated aspects of the enterprise were handled jointly by the US Army Ballistic Missile Agency and the Jet Propulsion Laboratory, and the launching was conducted at the Atlantic Missile Range, Cape Canaveral, Florida.

The radiation 'package' was very nearly identical to the one flown on *Pioneer III* except for one essential change—the Anton type 213 Geiger tube was encased in an additional shield comprising a closed end cylinder of lead of thickness 4.0 gm/cm² and an inner cylinder of stainless steel of thickness 0.6 gm/cm² (Fig. 1). On the basis of extensive laboratory calibrations at the State University of Iowa, the respective Anton 302 Geiger tubes in *Pioneers III* and *IV* had identical characteristics (that is, effective dimensions, shielding, etc.) to within ± 10 per cent (see ref. 1 for further detail).

The purposes of the radiation experiments in *Pioneer IV* were as follows: (a) a re-survey of the

Fig. 2. Plots of the projection of the trajectories of *Pioneer III* and *Pioneer IV* on a geomagnetic meridional plane (centred dipole model). Unit of distance $\rho_E = 6,371$ km.

intensity structure of the zones of trapped radiation around the Earth with special interest in temporal changes since December 6 and 7, 1958, (b) a crude determination of the absorptivity of the trapped radiation as a function of position in order to increase knowledge of its composition and spectral character (c) a re-determination of the effective extent of the geomagnetic field, (d) a search for magnetically trapped radiation in the vicinity of the Moon, (e) a re-determination of the cosmic ray intensity in interplanetary space (f) a search in interplanetary space for 'blobs' of plasma containing particles sufficiently energetic to be detected by the present equipment.

Flight of Pioneer IV

Launch from Cape Canaveral, Florida (28° 7' N 80° 7' W) at 05 11 UT on March 3, 1959.

Burn-out velocity ('space fixed') 11 08 km/sec.

The positional co-ordinates as a function of time were measured by the Jet Propulsion Laboratory tracking array to an uncertainty of some ± 5 km throughout the region of the trapped radiation and to a slowly increasing uncertainty thereafter. Table 1 lists representative values of the co-ordinates and Fig. 2 gives a plot of the trajectories of *Pioneers III* and *IV* in the vicinity of the Earth.

Telemetry

The array of Jet Propulsion Laboratory telemetry stations comprised receivers at Cape Canaveral, Florida (5 ft dish), near Mayaguez, Puerto Rico (10-ft dish) and at Goldstone Lake, California (85-ft dish), as before. In addition there was the valuable Jodrell Bank 250 ft dish through the courtesy of Prof A C B Lovell. The following is a summary of flight periods during which usable radiation observations were obtained.

Fig. 1. Physical arrangement of radiation detectors in conical payload of *Pioneer II*. Base diameter 23 cm. Total payload weight 6.1 km. The arrangement of *Pioneer III* was identical except for omission of the shield over the 213 tube.

| | |
|-------------------------|-------------------------|
| (a) Cape Canaveral | (d) Jodrell Bank |
| March 3 05 11-05 23 U T | March 3 06 31-12 24 U T |
| (b) Puerto Rico | March 4 07 52-08 08 |
| March 3 05 14-05 52 U T | 08 23-08 43 |
| 07 23-15 32 | 10 42-12 52 |
| (c) Goldstone Lake | March 5 05 41-12 58 |

| March 4 12 34-21 15 | |
| March 5 12 40-21 12 | |
| March 6 12 53-15 00 | |

From the point of view of the radiation experiment, the only serious loss of data occurred in the period 05 52-06 31 U T on March 3

Beginning at about 14 20 U T on March 6, the strength of the radio signal fell rapidly and no usable data were received after 15 00 U T. In view of the rapidity of the decline (in spite of a trivial rate of change of distance) and of its occurrence at about the end of the expected life-time of the batteries, it is presumed that loss of signal at about $x + 82$ hr was due to exhaustion of the mercury batteries in the power supply of the payload. The radial distance from the centre of the Earth was 658,300 km at 15 00 U T.

Radiation Observations

Due apparently to a high- g shock which was recorded during the launching phase, the high scaling factor (2^{17}) element of the 302's scaling circuit did not function in flight. This failure gives some cause

* Nearest approach to the Moon (approx.)

for uneasiness concerning the proper operability of all other elements of the payload. But we have been quite unable to find any evidence for any other malfunction and believe that the results reported below are trustworthy.

In Fig 3 is plotted the true counting rate, R , of the 302 Geiger tube as a function of time. Errors are insignificantly small except where error bars are drawn. The constant counting rate beyond 11 10 U T continues without significant variation to the outermost limit of observations. Also shown is the equivalent counting rate of the heavily shielded 213 Geiger tube. Normalization of the counting rates of the two tubes was done in pre-flight laboratory tests by subjecting them (both unshielded) to identical exposure in a beam of hard X-rays. The quasi-d.c. output of the 213 tube was measured by the audio-frequency of the subcarrier oscillator to which its amplifier was connected. A substantial temperature correction was necessary and was made by comparison with another, similarly located oscillator the input of which was digital and the temperature coefficient of which was similar. The temperature of the inner portion of the payload rose from a launching value of 15°C to an asymptotic value of $41.5 \pm 1.0^\circ\text{C}$ with a time constant of about 3 hr. The 302 system had zero temperature dependence over this range. In the lower left-hand corner of Fig 3 is plotted as a dashed line the ratio of the equivalent counting rate of the (shielded) 213 tube to that of the 302, this ratio is the apparent transmission, T , of the shield. The absolute value of T is uncertain by some ± 25 per cent of its value due to a combination of systematic errors.

In the time-period 06 31-06 53 U T the true counting rate of the 302 may lie either on branch A or on branch B . Such an ambiguity is intrinsic to the characteristic curve of apparent rate versus true rate of the system (cf ref 1) and can be resolved only by auxiliary data. The corresponding transmission curves are labelled A and B , respectively. Further discussion is deferred to the next section.

In Fig 4 the observations with the nearly identical 302 tubes of *Pioneer III* and *Pioneer IV* are shown as a function of radial distance from the centre of the Earth, ignoring differences of longitude and latitude.

Discussion and Interpretation

The most striking features of Fig 4 are the immensely greater quantity of trapped radiation in the outer zone on March 3, 1959, than on December 6, 1958, and the detailed structure present, especially in the 60,000-90,000 km region. It may also be noted that the observations by Vernov *et al*² with the Soviet cosmic rocket show that the situation on January 2, 1959, was similar to that on December 6 and 7, 1958. It is very suggestive that there was a substantial magnetic storm commencing at 02 15 U T on February 25 and that there were aurorae of strong intensity on February 25-28 and on March 1³. A special study of this event by Trotter⁴, of the High Altitude Observatory, makes it appear likely that at least three sequences of geophysical events starting on February 25, March 26 and April 23, respectively, were due to a solar M region. In any event, it is noteworthy that the flight of *Pioneer IV* was preceded by five consecutive nights of strong auroral activity, whereas the periods preceding the flights of *Pioneer III* and of the Soviet cosmic rocket were especially

Fig. 3 The counting rate observations during the early part of the flight of *Pioneer IV* (see text for further description of data)

quiet geophysical periods. Hence we suggest that the great temporal differences shown in Fig. 4 constitute the direct observation of the changes which occur in the outer radiation zone of trapped radiation following strong corpuscular emission from the Sun. If this view be accepted then it appears that the *Pioneer IV* observations provide the most persuasive, direct evidence thus far available for the solar origin of (at least) the outer radiation zone.

The inner peak of the *Pioneer IV* data (at 11 000 km) is about three times as intense as that of *Pioneer III*, but reference to Fig. 2 and to a large scale corrected plot as in Fig. 5 of ref. 1 shows that the inner zone was not significantly different on the occasions of the two flights. From this fact it may be concluded that the inner zone lying as it does in the region of strong geomagnetic field is relatively well isolated from direct solar influence.

The A-B ambiguity referred to in the preceding section in connexion with Fig. 3 (and Fig. 4) has not been conclusively resolved, but the following discussion strongly favours branch A as the correct one. The work of Vornov *et al.*⁸ makes it appear likely that in the outer zone the effects recorded by a detector under more than 1 gm/cm² of absorber are due to bremsstrahlung from the bombardment of the outer skin of the payload by electrons of energies less than 100 keV and with a spectrum steeply rising toward lower energies. If this be so then we note that transmission curve B of Fig. 3 not only has a quite unreasonable steepness but at its inner end has a value at least an order of magnitude greater than that measured in the laboratory with X-ray beams generated by elec-

trons of such energies. But transmission curve A is also together consistent with this radiation situation.

Adopting branch A and making use of our absolute X-ray calibrations of the 302 tube we find that the omnidirectional flux of electrons of energy greater than about 20 keV was of the order of $1 \times 10^{11}/\text{cm}^2 \text{ sec}$ at 30,000 km radial distance on March 3, 1959.

Also it is evident that the omnidirectional flux of electrons of energy greater than 200 keV did not exceed $1 \times 10^9/\text{cm}^2 \text{ sec}$ of electrons of energy greater than 2.5 MeV did not exceed $1 \times 10^8/\text{cm}^2 \text{ sec}$, and of protons of energy greater than 60 MeV did not exceed $1 \times 10^7/\text{cm}^2 \text{ sec}$.

The observations of *Pioneer IV* in the inner zone are unambiguous and show that about 30 per cent of the radiation

recorded by the 302 in the lower fringe of the zone also penetrates an additional 4.0 gm/cm² of lead and 0.6 gm/cm² of steel. The radiation becomes rapidly and progressively softer as one goes outwards from the Earth (Fig. 3). On the basis of two recent rocket investigations into the lower fringe of the inner zone⁹ and of our extensive *Explorer II* and *Pioneer III* observations¹⁰, we propose the following tentative composition of the trapped radiation present in the heart of the inner zone (altitude about 3 000 km on the geomagnetic equator): (a) electrons of energy greater than 20 keV—maximum unidirectional intensity $\sim 2 \times 10^9/\text{cm}^2 \text{ sec}$ steradian; (b) electrons of energy greater than 600 keV—maximum unidirectional intensity $\sim 1 \times 10^7/\text{cm}^2 \text{ sec}$ steradian; (c) protons of energy greater than 40 MeV—omnidirectional intensity $\sim 3 \times 10^6/\text{cm}^2 \text{ sec}$. The

Fig. 4 A comparative plot of the intensity data of *Pioneer III* and *Pioneer IV* (same scale of radial distance but ignoring differences of latitude and

latter two of these three figures are probably trustworthy to a factor of 2, the first one to a factor of 5. These results favour the neutron albedo hypothesis of origin of the inner zone of Vernov and others (cf discussion of ref 8), in respect to both the electron and proton components. A valuable discussion of the proton component has been given recently by Hess⁹. Some residual doubt may be felt as to the adequacy of the source function. It should also be noted that there is a rapidly developing body of knowledge on the sporadic, though relatively frequent (order of once a month) arrival of solar protons having energies up to several hundreds of MeV and intensities up to several orders of magnitude greater than that in the quiet cosmic ray beam¹⁰⁻¹³.

The conclusive identification of protons in the lower fringe of the inner zone⁷ and the resemblance of their spectrum there to that expected on the neutron albedo hypothesis⁹ has been accepted by many workers as conclusive evidence for the adequacy of this hypothesis. The quantitative considerations of Hess have also added strongly to this point of view. But it should be remarked that others, including Morrison, Gold and the present authors⁸, have some uneasiness in accepting a trapping-lifetime of several years, as is necessary for the success of the neutron albedo hypothesis. Thus, it is comforting to find that there is now an alternative source of protons (that is, direct solar emission) of suitable energy and intensity, provided a valid mechanism can be discovered for their admission into the inner zone. The reader is also cautioned to await observations during the oncoming period of minimum solar activity for illuminating evidence on temporal changes in both inner and outer radiation zones. Such a programme of observation is being undertaken by this laboratory.

Radiation Intensity Beyond 92,000 km

Pioneer IV provided a total of 45 hr of observation of the counting rate of the 302 Geiger tube in the range of 92,000–658,300 km from the centre of the Earth. (The counting-rate-meter circuit of the 213 was not sufficiently sensitive to provide a reading at any time during this portion of the flight.) The mean counting rate was calculated over each interval of time during which 256 (2⁸) counts were recorded. The distribution of counting rates in the 695 such intervals (each of about 4 min duration) has been studied in detail and it has been found that during no one of these intervals did the counting rate differ with statistical significance from the overall mean value of 1.090 ± 0.003 counts per sec.

A broader scale survey of the mean counting rate during larger segments of the trajectory was obtained by tabulating the times at which 'flips' of the major scaler (2¹³ = 8,192 counts per major 'flip cycle') occurred. The constancy of the counting rate during observed periods encouraged us to also 'count through' the unobserved periods of time, during which the payload was below the effective horizons of the receiving stations. During the longest such period six major flips were missed, and during the other two such periods four major flips were missed if it be assumed that the counting rate did not differ markedly when under observation and when not under observation. The results of this process are shown in Table 2. The trustworthiness of the tabulated counting rates during unobserved periods rests on *a posteriori* evidence as follows. On the assumption that the unobserved counting rates did not differ

Table 2 SUMMARY OF DATA FROM 302 TUBE BEYOND 92,000 KM BY FLIPS OF MAJOR SCALER (8,192 counts per flip cycle)

markedly from the observed ones, it is found in Table 2 that the unobserved counting rates differed by less than 1 per cent (that is, to within statistical uncertainty) from the adjacent, observed ones. The precision of this agreement in all three of the cases under consideration gives one a strong feeling of assurance that the counting rate of the 302 did not differ significantly at any time in the interval 92,000 to 658,000 km (March 3, 11 10 UT, to March 6, 15 00 UT) from its mean observed value of 1.090 ± 0.003 counts per sec. Several valuable conclusions follow from this analysis and are described in subsequent sections.

Paucity of Energetic Plasma in Interplanetary Space during March 3–6, 1959

On the basis of Table 2 and the foregoing discussion, it appears that, to high accuracy, the apparatus did not encounter any solar plasma containing particles sufficiently energetic to register efficiently on the 302 tube during some 76 hr of interplanetary flight.

Since the burden of evidence for the origin of the outer radiation zone of the Earth requires that plasma fly outwards from the Sun sporadically, it must be concluded that there happened to be a notable absence of such plasma during this period. This finding is especially striking in view of the strong geophysical activity during the preceding week. An alternative view is that the acceleration of the components of the plasma to sufficiently high energies to be registered efficiently by our equipment occurs

only in the geomagnetic field. The 302 tube in the present arrangement had an efficiency of about unity for protons of energy greater than 30 MeV, an efficiency of the order of unity for electrons of several MeV energy, and an efficiency of the order of 10^{-4} to 10^{-6} for electrons in the hundreds to tens of keV energy range (by way of their bremsstrahlung).

Hence during the 70 hr in question the time integrated flux of the higher-energy electrons and protons could not have exceeded $100/\text{cm}^2$ in an isolated burst during any one of the 0.95 observed 4 min intervals, could not have exceeded $1,000/\text{cm}^2$ in an isolated burst during any one of the three unobserved periods which had a duration of some 10 hr each, and could not have exceeded $2 \times 10^3/\text{cm}^2$ if distributed (with quite unbelievable uniformity) over the 70 hr period. The corresponding figures for 00 keV electrons, for example, are 4×10^4 times as great.

Lack of Influence of the Moon

Pioneer II's closest approach to the centre of the Moon was 00,149 km at about 23 00 τ on March 4 (Table 1). The telemetered signal was not being received at that time (see section on "Telemetry," and Table 1). But observations were obtained as close as 61,700 km and Table 2 and the accompanying discussion make it exceedingly unlikely that any significant change of counting rate occurred at any place in the vicinity of the Moon. The quantitative discussion of the preceding section is applicable here also. The geometrical shadow of the Moon on the apparatus was, of course, negligible. Hence this result suggests as an upper limit to the Moon's magnetic moment a value comparable to that of the Earth. This high an upper limit is, of course of little interest in the light of other probably more definitive knowledge which favours a much smaller value.

The Soviet cosmic rocket passed much closer to the Moon than did *Pioneer IV*, but unhappily the radiation intensity was unreadable at that range.

None the less, the determination of the Moon's magnetic moment by investigating its trapped corpuscular radiation on near approaches remains a technique of potential value. It will doubtless be wise to use a detector of the lowest feasible energy threshold and of the highest feasible sensitivity.

Re-determination of Interplanetary Cosmic-ray Intensity

On the basis of Table 2 and of our best present values of absolute geometric factor and efficiency of the 302 Geiger tube, we find for the interplanetary value of the omnidirectional cosmic ray intensity $J_0 = 1.8 \pm 0.3/\text{cm}^2 \text{ sec}$ during the period March 3-6 1959.

It may be noted that this value is one-half of that measured¹ on December 6 and 7, 1958, with *Pioneer III*. On the basis of a recent re-study of *Pioneer III* data, Snyder¹⁴ presents evidence that *Pioneer III* did not reach a sufficiently great distance to be entirely free of the influence of the geomagnetic field.

The *Pioneer IV* observations to very much greater distances (out to 103 Earth radii) are not subject to this uncertainty. Hence, we have considerably greater confidence in the new value quoted above though it should be understood that the counter will record protons of energy as low as 30 MeV and electrons of energy as low as 2 MeV. In any event, the measurement provides a solid upper limit to the total primary cosmic ray intensity in the general

astronomical vicinity of the Earth during early March 1959.

Using balloon borne equipment of discriminating character McDonald¹⁵ finds primary unidirectional cosmic ray intensities (corrected to zero atmospheric depth) at geomagnetic latitude 55° on July 2, 1958, as follows:

- Protons of energy greater than 230 MeV $0.000 \pm 0.0070/\text{cm}^2 \text{ sec steradian}$.
- Particles of energy greater than 158 MeV/nucleon 0.0149 ± 0.0012 .
- Sum of (a) and (b) 0.1099 .

An interesting comparison results from multiplying McDonald's sum of $0.11/\text{cm}^2 \text{ sec steradian}$ by 4π to obtain an estimate of the omnidirectional intensity of primary cosmic rays remote from the Earth. The result is $J_0 = 1.38/\text{cm}^2 \text{ sec}$. In so far as McDonald has been able to eliminate fast downward moving albedo his implied J_0 has the nature of a lower limit.

Vernov and Chudakov² report a value of $2.3 \pm 0.1/\text{cm}^2 \text{ sec}$ on January 2, 1959.

Effective Extent of the Geomagnetic Field

Our original interpretation of the *Pioneer III* observations¹ included the conclusion that the geomagnetic field loses its ability to trap charged particles at about 10 Earth radii. Snyder's discussion makes it appear that this was too small a value. The *Pioneer IV* observations (Fig. 4) indicate that geomagnetic trapping is significantly present out to as far as 14 Earth radii at least on a specific occasion. The loss of geomagnetic trapping efficiency is of course a loosely defined concept and there are doubtless marked fluctuations in the radiation regions at the outer fringes of the Earth's field.

Terrestrial Ring Current of Dolginov and Pushkov

Measurement of the scalar magnetic field intensity with the magnetometer in the Soviet cosmic rocket on January 3 1959, provided results of very great interest¹⁶ in the present connexion. The observed scalar field intensity fell gradually and progressively further below the curve representing the extrapolation of the surface field (using an eight-coefficient harmonic expansion and assuming a curl free field outside the solid Earth) in the radial distance range 14,000-21,000 km. At 21,000 km, the experimental curve was some 709 gammas below the 'theoretical curve (about 1,200 gammas). At greater radial distances the experimental curve rose toward the theoretical one and approximated to it beyond 20,000 km. These results imply a westward flowing ring current having the maximum value of the apparent current density at about 21,000 km radial distance from the centre of the Earth. By comparison with Fig. 4 of the present article it is seen that the most intense portion of the ring current lies in the inner side of our outer peak of radiation intensity and indeed in just the region in which the gradient of the volume density of charged particle kinetic energy has its greatest value. The understanding of the detailed relationship between the Dolginov-Pushkov ring current and the trapped radiation now becomes one of the most challenging and timely problems of geophysics.¹⁷

It may be speculated that the modification of the geomagnetic field by the ring current at about 3 Earth radii influences the structure of the radiation zones and perhaps contributes to the existence of the slot between the two zones.

Although the difference in the radiocarbon ages of the cranial bones and mandible is less than might have been expected in view of their contrasting states of preservation, it should be borne in mind that whereas a bone that has been buried in the ground for a few centuries may have become porous and 'sub-fossil' (with some absorbed fluorine), a bone of equal antiquity that has been preserved in air, for example on the floor of a dry cave, in a building or in a reliquary, may have retained the composition of 'recent' bone

Summary Radiocarbon dating has confirmed that the Piltdown skull (human) is Post-Pleistocene, probably less than 800 years old, and that the Piltdown mandible (orang-utan) is younger rather

than older, although possibly several centuries old. It is shown that these findings are not inconsistent with the skull being in 'sub-fossil' condition whereas the mandible (of very different origin) has the preservation of 'recent' bone

DISORGANIZATION OF THE SECONDARY STRUCTURE IN PROTEINS EXPOSED TO IONIZING RADIATIONS IN THE SOLID STATE

By DR. PETER ALEXANDER, L. D. G. HAMILTON and DR. K. A. STACEY

Chester Beatty Research Institute, Institute of Cancer Research, London, S W 3

LITTLE is known of the chemical and physical changes which occur when proteins are exposed to ionizing radiations under conditions where the effect is due to ionization within the protein molecules, that is, by 'direct' action. Detailed physical chemical studies have only been made on protein irradiated in solution when the reaction is indirect and due to free radicals. Most investigations of the direct effect have been confined to following the effect on their biological properties. It has been known for nearly fifteen years (cf. Lea¹) that the inactivation of dry enzymes by ionizing radiations is exponential with dose, which suggests that one event leads to loss of activity. The amount of energy which has to be supplied before this single reaction occurs is normally between 50 and 200 eV per molecule, depending on the enzyme. Quantitatively this suggests that nearly every primary ionization must be effective in destroying the biological activity. A primary ionization in an organic substance brings with it far-reaching chemical changes which usually affect several groups, but it seems highly improbable that the inactivation of all enzymes can be attributed to the chemical modification of a few amino-acid residues.

Biochemical studies² have shown that for many enzymes only a small part of the protein molecule is necessary, and that a large proportion of the amino-acid residues can be modified without loss of activity. Energy transfer processes which were recognized in organic macromolecules³ cause preferential attack of some groups, but the effect is not sufficiently selective to provide a mechanism for the inactivation of all enzymes by a single random event.

In a detailed study of the changes produced by irradiating solid crystalline bovine serum albumin (Armour Laboratories) containing 4-6 per cent of water with 2 MeV electrons, in the absence of oxygen we have found that the first effect of irradiation is to disorganize a large part of the molecule. This alteration in structure is not dependent on covalent chemical changes which follow ionization, but is the

result of a breakdown of many secondary valency bonds brought about by a single event which occurs on average for every 45 eV deposited and can therefore be associated with a primary ionization. The occurrence of a process of this type was predicted by Platzman and Franck and provides a mechanism for the inactivation of heat-labile enzymes of all types by ionizing radiations.

Opening up the Molecule

On irradiation the sedimentation behaviour of the bovine serum albumin in the ultracentrifuge changes⁴, and the decrease in normally sedimenting material follows an exponential relationship (Fig. 1), with a D_0 (dose required to change 63 per cent of all molecules) of 6.5×10^6 rads. This corresponds to an energy of 45 eV per molecule, which has to be supplied to affect on average one molecule. Change in sedimentation implies an alteration in molecular weight or in frictional resistance determined by the internal structure of the molecule. Light-scattering measurements show that with a dose sufficient to alter the sedimentation of 75 per cent of the molecules, the average molecular weight of bovine serum albumin rises only from 69,000 to 90,000. The ultracentrifuge measurements therefore indicate that a single event which occurs on average for every 45 eV of energy supplied changes the shape of the molecule. The assumption that the material sedimenting normally is native protein that has not been affected at all by radiation is confirmed by chromatography.

Evidence that radiation 'opens up' the molecule is provided by changes in the chemical reactivity of the constituent amino-acid residues. Bovine serum albumin contains seventeen disulphide groups per molecule, but at the isoelectric point none of these can be reduced to -SH groups⁵, or oxidized with peracetic acid to sulphonic acid groups⁶ under standard conditions. These groups are sterically inaccessible, but at pH values away from the isoelectric

Fig. 1. Effect of irradiation of 2 MeV electrons on some physical properties of bovine serum albumin. a, Fraction of bovine serum albumin showing changed sedimentation behaviour in the ultracentrifuge; b, fraction of bovine serum albumin insoluble in water; c, fraction of bovine serum albumin insoluble in $M/15$ phosphate buffer (pH 7).

point, or following denaturation, some become available for reaction. Exposure to 4 M guanidine hydrochloride at the isoelectric point makes available 70 per cent of the total present and this is further increased at alkaline pH values. On the other hand, a maximum of only 50 per cent are revealed by heat denaturation*.

Irradiation of the solid protein progressively increases the number of disulphide bonds available up to a maximum of 50 per cent (Fig. 2) (at the highest doses some of these are destroyed but within the dose range studied this is negligible). From the irradiated bovine serum albumin a fraction can be separated which is no longer soluble in water, and dissolves only in salt solution. In the water soluble fraction an increasing proportion of the disulphide bonds (up to 30 per cent) is revealed, and by applying a correction, on the basis of the ultracentrifuge measurements, for the presence of unchanged native material, the number of available groups in the molecules affected by radiation can be calculated (Fig. 2). This first radiation change can be described as an opening up of the molecule which changes the frictional properties but not the molecular weight, and reveals five disulphide bonds normally hidden. Since this change is associated with a single reaction which occurs when an average of 45 eV have been left in the molecule it can probably be ascribed to the production of one primary ionization.

Changes following a Multi Hit Dose Relationship

Another radiation effect is to render the protein insoluble in water while remaining soluble at high and low pH values and in salt solutions. To avoid 'trapping', the insoluble fraction is determined by measuring the protein which comes out of solution on dialysing out the $M/15$ phosphate buffer (pH 7) in which the irradiated protein is completely soluble. Fig. 1 shows that in the production of insolubility there is a pronounced threshold with dose and it fits

accurately a 'two hit curve'. This protein has a greatly increased light scattering molecular weight with average values ranging up to 350 000, but is highly polydisperse. These aggregates are not broken up, that is, the average molecular weight is unchanged, by solvents breaking hydrogen bonds or disulphide bonds and the cross links joining the molecules in the aggregates do not therefore involve either of these bonds. An interpretation consistent with all the facts is that a second ionization still further disorients the secondary structure of the molecule and thereby changes its solubility behaviour enabling cross links to be formed between molecules. In this extensively modified protein following the second ionization approximately half the disulphide bonds are available.

Further irradiation does not reveal any more disulphide bonds, but it does render the protein insoluble even in salt solution (curve C, Fig. 1). This heavily irradiated material dissolves only in 4 M guanidine hydrochloride. Probably extensive chemical alterations now involving about 5 per cent of all the amino acid residues made extensive intermolecular hydrogen bonding possible.

Chemical Changes

Chemical analysis of the irradiated protein for nine amino acids shows that the disappearance of amino acids (the nature of the products was not established) was linear with dose but that the sensitivity of the constituent amino-acids varies. Cysteine and dicarboxylic acids were the most sensitive, the aromatic and the basic amino acids came next in sensitivity and proline was the least affected by radiation of those studied. However the total range was less than a factor of three for example 10^4 rads affected 18 per cent of the cysteine, 13.5 per cent of the histidine and 8 per cent of the proline. Thus after a dose sufficient (that is, 45 eV/molecule) to open up the protein (only one molecule in five will have a single cysteine residue changed, one in six one histidine residue, and only one in two will have lost a carboxyl group).

The possibility that main chain polypeptide bonds are broken was tested by looking for low molecular

Fig. 2. Effect of radiation on the number of disulphide bonds in bovine serum albumin which can be reduced at the isoelectric point with β -mercapto-ethylamine. — Δ — For water-soluble fractions (that is including the molecules that have not been affected by radiation). — \bullet — for the insoluble fraction after correction for unchanged protein on the basis of the ultracentrifuge data. — \bullet — for fraction insoluble in water but soluble in salt solution.

weight fragments which could be recovered by dialysis of solution of heavily irradiated protein in 4 M guanidine hydrochloride. To guard against the possibility that broken fragments do not become detached because they are linked to the main molecule by disulphide bridges, the irradiated protein dissolved in guanidine hydrochloride was oxidized with peracetic acid, which breaks all disulphide bonds under these conditions. As no dialysable fragment could be found even after a dose of 2.5×10^5 rads it can be concluded that main-chain breaks play no part in the disorganization of the secondary structure.

Other chemical changes due to irradiation are the formation of carbonyl groups⁷ and of additional SH groups, as well as of a new amino-acid which has the same chromatographic behaviour as α -amino-*n*-butyric acid.

The presence of oxygen during the irradiations did not alter the first stage of 'opening up' or the destruction of amino-acids. However, the protein is rendered insoluble in water at lower doses and the greater radiation sensitivity of dry enzymes in oxygen⁸ may be due to the increased tendency for aggregation, or the production of main-chain breaks, which is facilitated by oxygen.

Mechanism of Enzyme Inactivation

Although bovine serum albumin has been studied by us in greatest detail, irradiation of solid trypsin, lysosyme and γ -globulin produces a very similar sequence of events, and we believe that the pattern outlined above applies generally to globular proteins. We interpret the changes which occur in a protein molecule by an ionization produced within it by an atomic particle as a two-stage process. First, the introduction of a positive charge disrupts the secondary structure over a large part of the molecule and introduces a new configuration. Secondly, the group in the molecule that has become ionized undergoes a chemical change. The latter are not randomly distributed and energy transfer processes increase the probability of damage in certain amino-acid residues. But these effects are not very selective and there is no indication that one particular type of side-chain will be altered in every protein molecule that had suffered an ionization. This precludes the possibility that loss of activity can be due to these chemical effects, and it seems much more plausible to relate inactivation to the initial disturbance of secondary structure as this is an immediate consequence of the ionization. An explanation is provided why ionizing radiations are much more effective (on a dose basis)

in inactivating enzyme⁹ than ultra-violet light or the indirect action of ionizing radiation (that is, H and OH radicals). Both these processes attack the protein chemically and alter side-chains, but they cannot disorganize the secondary structure directly.

We suggested tentatively¹⁰ that the sudden introduction of a positive charge breaks down induced dipoles and that the resulting temporary opening of hydrogen bonds allows the protein molecule to adopt a configuration having a lower free energy. The difficulty is to provide a mechanism by which the electric disturbance spreads over a significant part of the protein molecule. Platzman and Franck¹¹ were led from purely theoretical considerations to postulate that an ionization within a protein molecule changes the internal hydrogen bonding. They have discussed the probable range of the electrical disturbance in considerable detail and conclude that some fifteen to twenty hydrogen bonds can be severed in this way. Not enough is known of protein structure to predict whether the breakage of this number of hydrogen bonds is sufficient to produce the observed disorganization.

We wish to thank Mr W H T Davidson, of the Research Laboratories of Tube Investments, Ltd, for carrying out the irradiations, and Dr D Rosen for the ultracentrifugation.

This investigation has been supported by grants to the Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U S Public Health Service.

ORIENTATION OF ANIMALS TO POLARIZED LIGHT

By DR. H. KALMUS

Galton Laboratory, University College, London

WORK done or published during the past year concerning the orientation of animals—mainly arthropods—to the plane of polarization of light indicates the emergence of two different and, up to a point, contradictory approaches to these visual reactions. What may be called the orthodox view, gradually developed since von Frisch's original dis-

covery in 1948 of the ability of bees to orientate themselves with respect to the plane of polarization, has been ably summarized in a review article by Stockhammer¹. He considers the various types of arthropod eyes to be analysers and, in particular, thinks that the analysing faculty is not situated in the dioptric parts but depends upon special arrangements

of visual pigments in the receptor cells which, like a polarizing screen, would combine the properties of analysis and absorption.

Quite different conclusions have been drawn by Baylor and Smith (*Apis*)³, Bambridge and Waterman (*Mysidium*)², Burdon-Jones and Charles (*Littorina*)⁴, as well as by Kalmus (*Aedes*, *Drosophila*, *Thaumato myia*)⁵, who considered that the orientational behaviour of these various animals in the presence of polarized light might be explained either by purely external mechanisms, for example, by brightness patterns resulting from unequal scattering or reflexion from environmental objects, or by similarly unequal refraction from some faces of the dioptric apparatus, such as the surface of the eye. Neither of these interpretations requires analysing arrangements in the receptors.

The hypothesis that the rhabdomers of insect ommatidia are absorbing analysers is supported by the electro-physiological results and electron microscopical work quoted by Stockhammer¹, it has been further strengthened by the beautiful electron micrographs of insect eyes by Fernández Morán⁶, confirming that each rhabdome is built-up of numerous rod-shaped or tubular units which are oriented in regular array with their long axes more or less at right angles to the long rhabdome axis. In an opposite pair of rhabdomers in any ommatidium the rods or tubules show a similar orientation, but in adjoining rhabdomers their orientation differs. The orientation of the rods in the rhabdoms of neighbouring ommatidia may follow a regional pattern. At the level of the basement membranes 7-9 single sheathed nerve fibres exist in every ommatidium, indicating that separate signals might originate and be transmitted from each rhabdome. Some of Morán's figures show indeed a striking similarity to the 'star' model of an ommatidium, which von Frisch proposed many years ago for its analysing properties and provided it can be shown that the dichroitic visual pigment is incorporated into the rhabdome pattern in a regular and orientated manner, a physical basis would seem to exist for the assumption that the rhabdomers of insect eyes are indeed analysers. Thus equipped, the eyes of a bee should be able to distinguish between various areas in the blue sky which, during the day time, are fairly characteristic in their degree of polarization and direction of the plane of polarization, and which, according to von Frisch's experiments, they learn to recognize and navigating bees might use this information, rather as they use the position of the Sun when it is directly visible to them.

A transversal arrangement of rod-shaped structures seems to be of wide occurrence in the rhabdomers of arthropods, and a similar organization, found in the visual elements of the squid *Loligo*⁷ may occur in the molluscs. But in the rods and cones of vertebrates, the orientation of the structures to which the visual pigments are presumably attached is quite different and unsuitable for the detection of the plane of polarization of light impinging in the physiological direction.

Reactions to polarized light striking the rounded surface of some types of bulgy eyes at a skew angle can be expected to produce specific orientational effects in the absence of retinal analysers. Castilo (quoted by Stockhammer¹) has shown that a primitive type of such orientation occurs even in the absence of eyes, for example in fungi the cylindrical sporangiothecae of *Phycomyces* growing upwards

in a culture respond unequally to light of equal intensity but different planes of polarization. If light from two such sources strikes a sporangiotheca from opposite directions it will bend showing that the horizontally polarized light has a stronger effect than the vertically polarized light provided that the former is not the weaker in intensity by more than 10-15 per cent. In compound eyes, perception of polarization in oblique rays of light is only possible if the optical isolation of the individual ommatidia is not absolute, and if some light initially deviating from the ommatidial axis can produce visual effects. Such a situation is admitted by Stockhammer (quoting Waterman) to exist in *Limulus*, but denied by him for *Drosophila*, *Cladocera* and *Mysidium*. It may nevertheless occur in some commoner situations, for example, when insects fly under large areas of strongly polarized light from the sky bordering directly on dark areas in their visual field.

Selective reflexion of polarized light by structures in the environment of an animal provides another means of orientation, by producing brightness patterns. Such patterns being objective can be made visible to the human eye. In Baylor and Smith's⁵ experiments, bees were released into a flat chamber covered with clear glass and illuminated only by plane polarized light from above. Those bees which crossed the box tended to run preferentially at right angles to the plane of polarization when the bottom of the chamber was covered with some dark and reflecting material whereas over a white paper they did not show any directional preference. Under unpolarized light preferential directions of running were observed over a directionally biased dark reflecting surface. Bees running under a source of polarized light over the dark bottom of the chamber showed orientation even when the light could not strike their eyes directly, regardless of whether they were running on the dark surface or upside down on the glass. A periscope like arrangement showed that the intensity of the light reflected at sighting angles of 10-30° from the dark surface under polarized light varied greatly in different directions, and it is in fact easy to demonstrate that reflexion of polarized light from such a surface at low angles is strongly directional.

Making use of optomotor responses, I showed⁸ that various dipterous (*Aedes*, *Drosophila*, *Thaumatomyia*) and other insects followed the rotation of a 'Polaroid' sheet under vertical illumination only when they were moving on or over dark reflecting material, but did not react against a bright background. The existence of an objective brightness pattern in the light reflected at low sighting angles was again demonstrated and movement of this pattern can explain the optomotor responses.

Bambridge and Waterman² showed that orientational responses to polarized light of the marine crustacean *Mysidium gracile*, previously reported by them occur only when the water containing the animals is made turbid by the addition of yeast. No significant results were obtained in carefully purified sea water. The orientational responses of *Mysidium* under a vertical source of polarized light thus seem dependent upon the discrimination by these crustaceans of differences of intensity in light scattered horizontally.

Burdon-Jones and Charles⁴ have shown that photonegative winkles of the species *Littorina littorea* move along the plane of polarization of light from an overhead source when it strikes them directly from above, even when the animals are allowed to

crawl on a small ball in such a way that no light is reflected from the substrate. The snails, however, orientate themselves equally well when their eyes are shielded from direct light and the only light they can see is reflected from the substrate. Photopositive individuals orient themselves at right angles to the plane of polarization. Burdon-Jones and Charles believe that in either situation the snails orient themselves with respect to a pattern of light and shade, perhaps arising from the Fresnel laws of refraction of plane polarized light, and that the animals do not possess any special powers of analysis whereby they could discern the polarized light in another way.

Our knowledge of orientational behaviour in polarized light is as yet too scanty and insufficiently integrated to permit of a general resolution of the apparent contradictions, and in fact it is not at all certain that similar mechanisms operate in all situations where polarized light has been shown to produce orientational effects. Some suggestions might, however, be useful. One might distinguish between phototactic responses of animals which are correlated with the plane of polarization of light and the more complex perception and consequent utilization of polarization patterns in the blue sky as inferred for the bee by von Frisch. Indirect directional effects of overhead sources of polarized light striking certain structures in the natural or experimental environment or in the dioptric apparatus and resulting in objective brightness patterns might frequently provide a sufficient explanation for the orientational behaviour of animals whether they in fact possess retinal receptors with analysing properties or not. On the other hand, it is rather difficult to see how orientation with respect to small areas of blue sky could occur without

such receptors. However, in many situations brightness gradients and polarization patterns in various parts of the blue sky are associated, and bees might in fact orient themselves to the former. Furthermore, reflexion patterns caused by sunlight will often have their maximum brightness in the same azimuth as the Sun itself and the same applies to polarized light from a small area of sky reflected in a substrate. Thus the position of the Sun might be perceived by a bee directly or, when the Sun is invisible, its azimuth might be inferred from a brightness maximum in an area of the sky or a reflecting background. The reactions of *Littorina* in the different conditions described above conform with such an explanation and might perhaps be taken to support this speculation.

Another aspect of the orientation to polarized light might be mentioned finally, namely, its role in the life of the animals. It is probably safe to assume that many of the observed reactions are merely experimental artefacts. However, it is possible that, in other instances, orientation to sources of polarized light—however it works—may be of great ecological importance. Progress in this field will depend on the careful weighing of evidence from such diverse techniques as electron microscopy, electrophysiology, photometry and not least from observations of the animals concerned.

OBITUARIES

Sir Ian Clunies-Ross, C.M.G.

SIR IAN CLUNIES-ROSS, chairman of the Commonwealth Scientific and Industrial Research Organization (Australia), died on June 20 in Melbourne, Victoria, in his sixty-first year. He was born at Bathurst, New South Wales, and educated at Newington College, Sydney. He graduated as bachelor of veterinary science from the University of Sydney in 1921 and was awarded the degree of doctor of veterinary science of that University in 1928. After graduation he was awarded a Walter and Eliza Hall Veterinary Research Fellowship and undertook postgraduate studies at the London School of Tropical Medicine and at the Molteno Institute, University of Cambridge. In 1928 he went to Japan for parasitological studies at the Institute of Infectious Diseases at Tokyo Imperial University.

In 1925 Clunies-Ross was appointed lecturer in parasitology in the University of Sydney, and in the following year Council for Scientific and Industrial Research parasitologist. When the C.S.I.R. McMaster Animal Health Laboratory was established in 1931 through the munificence of Sir Frederick McMaster, Clunies-Ross was appointed as the first officer-in-charge. He held this position until 1937, when he was appointed Australian representative, and later chairman, of the International Wool Secretariat in London.

Early in his career Clunies-Ross specialized in veterinary parasitology—a much-neglected subject in Australia at that time. He saw clearly its great economic significance, especially to the sheep and wool industry, and applied himself to it so effectively that he quickly became one of the world's leading scientists in that field. Although most of his work dealt with helminthiasis of sheep, his interest ranged widely among parasitological problems of other domestic animals and of man. He brought to all his work a broad outlook and a depth of scientific understanding which inspired his colleagues and immediately won the confidence of the livestock industries. Between 1923 and 1937 he published some sixty articles as sole author and a further fifteen as senior author; in addition, he was co-author of a text book on the parasitic diseases of sheep.

Realizing at the outset that the clarification and definition of the multiple and diffuse problems of ovine helminthiasis were essential if effective means of therapy and prophylaxis were to be devised, he instigated widespread surveys of the incidence and distribution of the major worm parasites of sheep, and of the associated climatic and other factors which determined their clinical significance. Thus, for the first time a sound basis was laid for studies on epidemiology, host-parasite relationships and selective anthelmintic treatment. He and his colleagues fol-

lowed up with great vigour and enthusiasm the advantage this clearer understanding of the problem gave them, and progress flowed from it rapidly.

Among his many outstanding contributions, Clunies Ross was the first to record the effect of copper sulphate on closure of the oesophageal groove in sheep. This opened up a new approach to anthelmintic treatment. It was he who, by well planned field trials, removed the fears of graziers that more intensive stocking of sheep on improved pastures would result in heavy losses from parasitism. This led him to investigate the effects of improved pastures on the quantity and quality of wool production. It was widely held that the wall being of the Merino and the quality of its wool depended on extensive, highly selective grazing, and that intensive grazing on the narrow range of species in sown pastures would result in coarse and inferior fleeces. Clunies Ross clearly demonstrated that not only can Merino sheep tolerate intensive grazing but also that they respond to the higher nutritional levels of sown pastures by producing much heavier fleeces with little change in fibre diameter.

Clunies Ross was an inspiring research leader. He had the capacity to see problems clearly, to ask the crucial questions and to find ways of answering them effectively by laboratory or field experimentation. His interest in veterinary research, however, and his choice of problems was always greatly influenced by his genuine love of animals. This is well exemplified by the work in tick paralysis of dogs, which was one of his most original and successful investigations. He was then living in a part of Sydney where many hundreds of pet dogs died annually from the disease. He was so moved by their suffering and by the distress of their owners that, in addition to all his other work, he took it upon himself to study this problem also. Within three years he elucidated the epidemiology of the disease traced its cause to a toxic factor in the salivary gland of the engorging female tick (*Ixodes holocyclus*), and prepared an antitoxic serum of high curative value. This was typical of him, his interest was not in gaining new knowledge for its own sake but for the use which could be made of it. Having once gained it, he used to the full his great gifts as a writer and public speaker to explain its significance to all who could apply it with advantage.

Clunies Ross's active personal research had to be laid aside when he joined the International Wool Secretariat. Although he was appointed professor of veterinary science in the University of Sydney in 1940, he had little opportunity for scientific work as he was called upon to serve during the war years as director of scientific personnel in the Commonwealth Directorate of Manpower and with the Department of War Organization of Industry as an adviser on the pastoral industry. The War interrupted his scientific career, but it gave him opportunities to use his unique knowledge of Australian agriculture and his outstanding powers as a speaker and publicist to encourage and assist the remarkable growth of science and education in Australia during the years which followed. In 1946 he joined the Executive Committee of the Council for Scientific and Industrial Research and in 1949, when the Council was reorganized as the Commonwealth Scientific and Industrial Research Organization, Clunies Ross became its first chairman. He continued to maintain his close interest in the wool industry and played a large part in procuring the funds which enabled CSIRO to build up a major effort in sheep and

wool research and wool textile research. Throughout the pastoral industries his many friends had confidence in his judgment, and with their help and with the backing of the Government he had the satisfaction of seeing towards the end of his life, a large body of scientists working enthusiastically on many problems of great national importance. The major contributions which CSIRO has made to the agricultural development of Australia have been largely due to his outstanding and inspiring leadership.

Clunies Ross had many interests outside his scientific work. The field of education was one in which he played a big part, and he was outspoken on the need for retaining breadth and liberalism in education. He stressed repeatedly the dangers inherent in the increasing specialization of modern scientific and technological careers. He played a large part in persuading the Government to set up the Murray Committee on Australian universities and made a major contribution to its outstanding report. He was deputy chancellor of the University of Melbourne and a member of the Council of the Australian National University. For many years he was active in the work of the Australian Institute of International Affairs and was well known as a public speaker on foreign affairs. He was particularly interested in the relations between Australia and its northern neighbours. As chairman of the International House of the University of Melbourne a hall of residence in which Australian and overseas students live together, he was instrumental in making the idea a reality.

Clunies Ross was made C.M.G. in 1954, and in the same year he was created a knight bachelor. He was a Foundation Fellow of the Australian Academy of Science. He was awarded the honorary degrees of doctor of laws by the University of Melbourne, and doctor of science by the Universities of New England and Adelaide. He is survived by Lady Clunies Ross, three sons and one daughter.

At the memorial service held in Scots Church, Melbourne, shortly after his death Prof. J. D. McCaughey, Master of Ormond College University of Melbourne, made a fitting tribute to his memory. He expressed in those simple terms the feelings of his many friends and colleagues throughout Australia and overseas. "But in and through these achievements, it is Ian Clunies Ross the man whom we remember with admiration, with respect and with affection to-day. His capacity for work must have been enormous to die at sixty is young yet into those years was packed an astonishing variety and depth of interests. He lived a heavily committed life, yet, I suppose, that many of us in this Church think of him, with gratitude, as one who had time for friendship. He accepted us with a smile. It must have been given to few who have lived so fully yet to be loved by so many."

F. W. G. WHITE
D. A. GILL

Dr V. Korenevsky

DR V. KORENEVSKY who died suddenly on July 9, was born in 1880 in Russia and graduated from the Imperial Military Medical Academy in St. Petersburg in 1903. After military service in Manchuria during the Russo-Japanese War he worked in Vetchnikov's department at the Pasteur Institute in Paris and in Pavlov's laboratory in St. Petersburg.

In 1911 he was appointed professor of experimental pathology in the Imperial Military Medical Academy and remained there until the Revolution. His disagreement with the policy of the newly formed Soviet Government made it necessary for him to leave St Petersburg and he escaped to south Russia, where he served as a doctor with the White Army for about a year. After the defeat of the White Army he made his way to England and in due course became naturalized.

During 1929-45 he was a member of the staff of the Lister Institute. Afterwards he established the Oxford Gerontological Research Unit, with the support of funds provided by Lord Nuffield, and remained there until his retirement in 1952.

The bulk of Korenchevsky's work between the Wars was primarily endocrinological and was concerned with studies of the effect of sex and thyroid hormones, separately and in combination, not only on the reproductive organs but also on the other organ systems of animals of different ages. His work was characterized by a very close attention to detail, the use of first-class histological techniques and insistence on the need for healthy experimental material. Korenchevsky regarded this work as a necessary preliminary to provide a rational basis for use of hormones in mitigating some of the degenerations which occur with ageing.

Dr Korenchevsky will be especially remembered, however, for his pioneer achievements in stimulating interest in the field of gerontological studies. His own concern with the problems of ageing went back to the early years of the century when he visited Russian infirmaries for old people, and during his stay with Metchnikoff in Paris he worked on the

effects of gastro-intestinal autointoxication. He always remained convinced of the value of Metchnikoff's theory, and he reaffirmed his belief in the importance of autointoxication as an ageing factor in several recent publications.

By the late 1930's he felt that the change in the climate of opinion, for which he had been waiting, had come and that vigorous efforts to emphasize the need for gerontological research might at last be effective. He therefore set out with the intention of developing an International Association of Gerontologists which would be responsible for investigations in all branches of the subject. His efforts were just beginning to bear fruit when the outbreak of the War in 1939 brought them to an end for the time being.

After the War, his retirement from full-time active laboratory work allowed him to extend his campaigning even more vigorously. He was an outspoken advocate of the importance of gerontology, and in his missionary ardour he sometimes appeared intolerant of the ideas of others. But any irritation engendered by his interventions were always more than outweighed by their stimulant effect, and it was clear to everyone that he was never seeking any personal advancement but only the benefit to his chosen subject which recognition might bring. The results of his lifetime of strenuous effort will be found not so much in his large series of careful scientific publications as in the numerous national societies for the study of problems of ageing throughout Europe and the Americas, in the International Association of Gerontology and in the enhanced status which the subject has now acquired.

P L KROHN

NEWS and VIEWS

Chief Scientist to the Ministry of Power

Dr C M Cawley, CBE

DR C M CAWLEY, CBE, has been appointed chief scientist to the Ministry of Power in succession to Sir Kelvin Spencer, who has retired from the public service. Dr Cawley, who is fifty-two, has been at the headquarters of the Department of Scientific and Industrial Research for the past six years, where he has been responsible for administering general policy in relation to the work of the Department's research stations, and to grants made by the Department to the universities and other bodies, for the promotion of research and the training of research workers. He is a University of London graduate with first-class honours in chemistry and joined the Scientific Civil Service in 1929, serving on the staff of the Fuel Research Station until 1953. He will take up his new appointment at the Ministry of Power in the early autumn.

Ministry of Supply Appointments

Dr N J L Megson

DR N J L MEGSON has been promoted to be deputy chief scientific officer and appointed director of materials, research and development (air) at the Ministry of Supply Headquarters. Dr Megson studied chemistry at the University of Birmingham under Prof G T Morgan. He obtained his BSc in 1923 and his MSc in 1925. He joined the Chemical Research Laboratory, Department of Scientific and

Industrial Research, in 1927, as head of the Synthetic Resin Section and carried out fundamental and applied work on various aspects of polymers, particularly in the phenolic resin field.

On the outbreak of war he was appointed to the Ministry of Supply as advisor on plastics and later became assistant director in charge of the Advisory Service on Plastics, Rubber and Paints, concerned with development and application of new and special materials for a variety of Service equipment. In 1949 he was awarded the degree of DSc by the University of Birmingham for a thesis entitled "Polymer Investigations". He became head of the Chemistry Department, Royal Aircraft Establishment, in 1951, responsible for research and development of non-metallic materials associated with aircraft and airborne equipment. Dr Megson is the author of fifty or sixty publications, including a book, "Phenolic Resin Chemistry", and he has recently been awarded the Gold Medal of the Plastics Institute. He succeeds Dr H Sutton, whose direct contribution to and sponsorship of work on light metals for aircraft construction has brought him deservedly wide appreciation.

Dr B G Dickens, CBE

DR B G DICKENS, who has been promoted to be chief scientific officer and appointed as director general of atomic weapons in the Ministry of Supply, brings to that post wide knowledge of

operational problems and experience of weapon development. He obtained a first-class honours degree in physics in the University of London and entered the Civil Service in 1932. He served at the Royal Aircraft Establishment until 1936 and was then transferred to Air Ministry Headquarters. He was attached to the Royal Air Force Station at Biggin Hill as the scientific officer associated with the now well known air defence experiments which were initiated by Sir Henry Tizard and his committee. When he returned to the Air Ministry he was still closely concerned with air defence problems and in addition became joint secretary of a committee under Sir George Thomson to advise the Government on the practicability of an atomic bomb. He was for a time responsible for arranging the officially sponsored work in various universities. In 1941, he was put in charge of the newly formed Operational Research Section Bomber Command, which analysed the Command's operations from all aspects and made contributions to the knowledge available to the Command staff, which led to increased efficiency and improved operational methods. After the War at Air Ministry Headquarters he assisted in the establishment of the peace-time organization of operational research in the Royal Air Force. During 1948-1952 he was director of technical personnel administration in the Ministry of Supply where his main work was the planning of recruitment of technical staff particularly in the fields of guided weapons and atomic weapons. He returned to the Air Ministry as deputy to the scientific adviser, whose duties were to advise the Air Staff on the influence of the new weapons on strategy and tactics and to direct operational research. He was then appointed director of guided weapon research and development in the Ministry of Supply, where he was responsible for much of the Ministry's research and development work on guided weapons for all three Services. In a reorganization in 1958 his work was concentrated on the development of the British intermediate range ballistic missile.

Mr P A Hufton

Mr. P A Hufton has been promoted to become chief scientific officer and appointed head of the Aerodynamics Department at the Royal Aircraft Establishment in succession to Mr L F Nicholson, who is the new director general of scientific research (air), Ministry of Supply. Mr Hufton graduated in engineering at the University of Manchester in 1933 and obtained his M.Sc. degree a year later. He joined the Aerodynamics Department of the Royal Aircraft Establishment in December 1934 and after working for a short period on low speed research transferred to the Aerodynamic Research Flight where he remained until March 1946. Before the War, he worked part time with C N H Look at the National Physical Laboratory on propeller theory and experiments. During the War he was responsible for take off and landing research, particularly for heavily loaded aircraft, rocket assisted take-off, development and flight testing of high lift devices, and work on carrier landings for the Royal Navy. In the spring of 1946 he moved to the Aeroplane and Armament Experimental Establishment at Boscombe Down as superintendent of performance. He returned to the Aerodynamics Department, Royal Aircraft Establishment, Farnborough, in October 1953, in charge of the Supersonics Division and moved to the Royal Aircraft Establishment at Bedford as head of the Aerodynamics Division in September

1957. A year later Mr Hufton became chief superintendent of the Royal Aircraft Establishment at Bedford in succession to Mr L H G Sterne.

Chemistry at the Royal College of Science and Technology, Glasgow

Prof F S Spring, F.R.S.

Prof F S Spring, who is retiring from the chair of chemistry in the Royal College of Science and Technology, Glasgow, graduated at the University of Liverpool under Sir Ian Heilbron and received his first appointment in 1930 in the University of Manchester, where he remained for sixteen years. After Sir Ian Heilbron moved from Liverpool to the chair of organic chemistry in Manchester he and Spring worked in close collaboration over a number of years and made notable contributions to our knowledge of the chemistry of the sterols, vitamin D and the triterpenes. During this period Prof Spring's work was particularly associated with the structure of ergosterol and calciferol, and with the β amyrin group of triterpenes. Prof Spring was elected to the Freeland chair of chemistry at the Royal Technical College (now the Royal College of Science and Technology) in Glasgow in 1946. Here he has developed a flourishing school of research in the chemistry of the triterpenes and of certain heterocyclic systems. Prof Spring was a Tilden Lecturer of the Chemical Society and was elected a Fellow of the Royal Society in 1952.

Prof P L Pauson

Dr. PETER LUDWIG PAUSON who has been appointed to succeed Prof Spring graduated at the University of Glasgow with first-class honours in chemistry in 1940 and proceeded to Sheffield as holder of a Henry Ellison Research Fellowship. There he worked under R D Haworth on purpurigallin and was awarded the degree of Ph.D. in 1949 having already shown his versatility by giving good service as temporary assistant lecturer in inorganic chemistry. He spent the next four years in the United States first as assistant professor at Duquesne University, Pittsburgh, then as Research Fellow successively at the University of Chicago and at Harvard. It was then that he discovered the novel sandwich compound, diacylopentadienyl-iron, usually known as ferrocene. The interest aroused by this substance and its relatives was such that, less than four years later Dr Pauson could publish a timely review article on work in this field, with eighty-eight references. He returned in 1953 to the University of Sheffield, where he now holds the post of reader, vigorously pursuing the investigation of these remarkable substances, both as quite exceptional cases of metallic co-ordination and as organic aromatic systems of a new type.

Nuclear Physics at the University of the Witwatersrand

Prof J P F Sellschop

Dr. J P F SELLSCHOP has been appointed to the chair of nuclear physics at the University of the Witwatersrand as from July 1. He will continue to be director of the University's Nuclear Physics Research Unit to which position he was appointed in 1950. Prof Sellschop who at the age of 20 became the youngest professor in the University, is at present in Britain carrying out research at the Atomic Energy Establishment at Harwell for six months. He is a member of the Research Advisory Committee of the

Atomic Energy Board and represented the Union at a seminar on atomic energy and its educational problems which was held in Saclay, France, under the auspices of the International Atomic Energy Agency in July. Prof Sellschop was also an official delegate to the second International Conference on the Peaceful Applications of Atomic Energy in Geneva last year. Born in Luderitz, South West Africa, Prof Sellschop received his early education at Christian Brothers' College, Pretoria. He then became a student at the University of Pretoria and received the B.Sc. degree there *cum laude* in 1950. After working at the National Building Research Institute in Pretoria for two years he was awarded an H.B. Webb scholarship and enrolled in the Merensky Institute of Physics at the University of Stellenbosch and in 1952 received the degree of M.Sc. *cum laude*. He then joined the Bernard Price Institute of Geophysical Research, later successfully reading for the Ph.D. degree in the nuclear physics group of the Cavendish Laboratory, Cambridge, as holder of a postgraduate scholarship awarded by the Shell Company of South Africa Ltd. in 1954.

Microbiology at Sheffield

Prof S. R. Elsdon

DR SIDNEY REUBEN ELSDEN has been appointed to the newly created chair of microbiology in the University of Sheffield, as from October 1. Dr Elsdon was educated at the Cambridge and County High School for Boys and the University of Cambridge. He graduated B.A. in 1936 and obtained first-class honours in both parts of the Natural Sciences Tripos. During 1937-38 he worked under Dr Marjory Stephenson in the Department of Biochemistry at Cambridge and was then appointed assistant lecturer, and later lecturer, in physiology in the University of Edinburgh. In 1943 Dr Elsdon joined the scientific staff of the Agricultural Research Council's Unit of Animal Physiology at Cambridge. He went to Sheffield in 1948 as senior lecturer in microbiology in the Department of Bacteriology and in 1952, when the University created a separate Department of Microbiology, Dr Elsdon was appointed head of the new Department. He has also been honorary director since 1952 of the Agricultural Research Council's Unit of Microbiology, which is housed in his Department. Dr Elsdon's Department has received generous support from the Rockefeller Foundation, and the Agricultural Research Council Unit has also received a grant from the Kellogg Foundation.

New Commonwealth Institute Building

PLANS for a new building for the Commonwealth Institute were made public on June 17. The new premises, which will replace the present accommodation in the Colcutt building in South Kensington, will be erected on a 3½-acre site at the southern end of Holland Park, fronting Kensington High Street, at an estimated cost of £725,000. Work will start next spring and is scheduled for completion in 1962, when the removal of the Institute from its present building will be necessitated by Government plans for the expansion of the Imperial College of Science and Technology. The new Institute will consist of a main exhibition block with a wing on the western side. In the wing will be housed offices, a restaurant, a reception centre and dining space for visiting school parties. A large reception room for the Commonwealth Students' Club and for confer-

ences and social occasions, a reference library and reading-room, a cinema to seat between 450 and 500, and a gallery specially designed for temporary art and other exhibitions are also included in the plans. The architects are Messrs Robert Matthew and Johnson-Marshall. The Commonwealth Institute is the major centre in the United Kingdom for information about the Commonwealth nations and their Dependencies. Founded as the Imperial Institute in 1887, it has occupied its present accommodation in the Colcutt building since 1893. The name was changed from 'Imperial' to 'Commonwealth' Institute by the Act of 1958.

The British Non-Ferrous Metals Research Association

THE opening of the latest addition to the laboratories of the British Non-Ferrous Metals Research Association by Sir Alexander Fleck on May 13 is a further step in the progress of an Association which has grown in activity and reputation ever since it was first established some thirty years ago. This reputation in the field of non-ferrous metallurgy is acknowledged not only in Britain but also abroad. The restoration of the laboratories after serious war damage suffered serious delays, and with the increase in the Association's work and the resulting congestion, the decision was taken in 1957 to complete the building plans which had been formulated some twenty years earlier. The block now opened adds some 12,500 sq ft of floor space, bringing the total to about 53,000 sq ft. It contains now corrosion laboratories, a large new metal finishing shop, extensions to the physics laboratories and to the foundry. Together with these a new council chamber and badly needed offices for the senior staff add considerably to the administrative amenities.

The Metropolitan-Vickers Nuclear-Metals Laboratory

IT was with the view of ascertaining the effects of irradiating metals that Metropolitan-Vickers Electrical Co. Ltd. decided to extend the existing facilities of the Research Department by building a Nuclear-Metals Laboratory. The Laboratory is equipped for the examination and testing of irradiated components and materials ranging up to a complete fuel element having an activity of the order of 10 kc. It is provided with two large concrete caves, and a train of five interconnected lead-walled cells is used to receive large irradiated objects. Essentially the caves are constructed of barytes concrete blocks. The air in the caves is arranged to be maintained at a slightly lower pressure than that in the open laboratory, thus ensuring that no air-borne radioactive dust can escape. Remote control manipulators enable the operations to be carried out inside the caves from outside the walls. The new laboratory will primarily be engaged on work for the Associated Electrical Industries—John Thompson Nuclear Energy Co., Ltd., and on work under contract for the U.K. Atomic Energy Authority. The scope of work will be concerned not only with investigations into the irradiation effects on constructional materials such as graphite and steel of various types, but also with establishing the behaviour of metals such as magnesium, zirconium, beryllium, etc., and of thermal and electrical insulation materials. A highly organized health physics service is maintained to safeguard the operating staff against all the hazards involved.

Sponsored Research in Great Britain

FACILITIES for sponsored research in Great Britain were increased by the formation in 1957 of the Arthur D Little Research Institute which has laboratories at Inveresk, Midlothian. The Institute is a non-profit-making organization registered in Great Britain as a company under the Friendly Societies Act, and although the two concerns are separate, it operates in close association with a similar group in the United States, Arthur D Little, Inc., of Cambridge, Mass. The Institute has now issued its first annual report from which readers may gain some idea of the scope and objects of the new venture. With Lord Bilsland as chairman of the Board of Directors, and with Dr F N Woodward as director of research, the Institute has been concerned with several projects, all of which are being treated with special reference to the fundamental scientific background. The results will normally be given open publication when the work is complete and interim accounts of the various projects are given in this annual report. These projects include investigations of the sodium derivatives of sucrose and of their condensation with a variety of organic halogen compounds, studies on the mechanism of the formation of isotactic polymers, the development of rapid methods for assessing the effectiveness of potential corrosion inhibitors, studies on the mechanism of inhibition of corrosion by electrochemical methods, and investigations into the modification of wood cellulose by chemical methods. In addition, the report refers to lectures, publications and other scientific activities organized by the staff of the Institute. It will be of great interest to all those who wish to know more about this new development in sponsored research and its place in the general organization of research in Great Britain.

Nuclear Studies in the United Kingdom

THE Science Department of the British Council has issued its third list (May 1959) entitled "Nuclear Studies". This is a concise catalogue of courses in pure and applied sciences concerned with the use and development of nuclear energy. It is issued primarily as a guide for the overseas student who wishes to undertake specialized formal training in the United Kingdom. Consequently it includes only full time courses, generally of one week or more in duration, and is not concerned with research topics or with the courses which may be regarded as forming part of a normal first degree course. Although the list has appeared too late for application to be made for many of the courses during the academic year 1959-60, it serves to direct inquiries for courses in 1960-61. Further information can be obtained from the Science Department of the British Council, 65 Davies St., London W 1.

Building Research in New Zealand

IN recent years, a number of fields of investigation relating to the building industry in New Zealand have been pursued independently in various organizations and laboratories in which the main interests have been in quite different fields. The Dominion (Chemical) Laboratory has investigated paints and local building materials, the New Zealand Forest Service has carried out work on timbers both indigenous and exotic, suitable for building, the Pottery and Ceramics Research Association has investigated the appropriate use of brick constructions

for earthquake conditions, and the Dominion Physical Laboratory has done some valuable work on methods of domestic heating, thermal insulation and related physical problems. But there has been no co-ordination between these diverse efforts, nor any institution wholly devoted to problems of the building industry.

This anomalous state of affairs is now to be abolished with the establishment of a Building Research Bureau, which is being sponsored by a joint committee of the New Zealand Master Builders Federation and the New Zealand Institute of Architects. Dr Lyndon Bastings has been appointed the first director. It is intended initially to set up a library and an information service, but as funds allow, it is hoped that laboratories and other practical facilities will follow in due course. The address of the new Bureau is Construction House, 66 Murphy Street, Wellington, N 1, New Zealand.

Postgraduate Courses at the Imperial College of Science and Technology, London

ADVANCED postgraduate study has long been a special feature of the work of the Imperial College of Science and Technology, University of London. As new types of technology emerge—of which nuclear power and soil mechanics are notable recent examples—they open up possibilities of study which must remain outside the scope of any course for a first degree but which are properly within the field of university teaching. The postgraduate courses at the College have been greatly increased in number in recent years to meet the wide range of technological development. Postgraduate courses provide the opportunity for students including many who have already spent a year or more in industry, to further their knowledge in a particular specialized field and at the same time to learn from experts their experience of the application of this knowledge in industry. Details of the courses are set out in an impressive handbook published by the College (*Postgraduate Courses, 1959-60*, Pp. xi+111, London: Imperial College of Science and Technology, 1959); the list should give considerable satisfaction to all who are concerned with Britain's place in the world of technology. Many of these courses have been accepted by the Department of Scientific and Industrial Research as suitable for the tenure of advanced course studentships. Grants for the courses related to agricultural science are awarded by the Ministry of Agriculture Fisheries and Food. The courses are assisted by industry in particular a number of firms support the work of the advisory committees in concrete technology and technical optics and provide bursaries for the respective courses.

Sandwich Course in Executive Development

THE Department of Commerce and Management of Sheffield College of Technology is to provide a sandwich course in executive development commencing in November 1959. The purpose is to provide for the young manager and potential manager a fully integrated plan of executive development, by bringing together in one scheme both education for management within the College and general and vocational managerial experience in his working environment. Full time attendance at the College will be required for approximately fifteen weeks during each year of the course and will be spread over a period of two academic years. Only students already engaged in industry and individually

sponsored by their employers will be accepted into the course. Further information can be obtained from the Head of the Department of Commerce and Management, 1, Melbourne Avenue, Sheffield, 10

Developmental Biology

THE first number has recently appeared of a new journal, *Developmental Biology*, published by the Academic Press, and produced by an editorial board consisting of Prof J Brachet, Prof E Hadorn, Dr P Weiss with Prof M V Edds of the Department of Biology, Brown University, as managing editor (*Developmental Biology*, Vol 1, No 1, April 1959 Pp x+124 Volume 1 (6 issues) 14 dollars New York and London Academic Press, Inc., 1959). The manuscripts in English should be sent to *Developmental Biology*, Department of Biology, Brown University, Providence, Rhode Island, U S A those in French to J Brachet, Laboratory of Animal Morphology, University of Brussels, Brussels, Belgium, and those in German to E Hadorn, University of Zurich, Switzerland. Many of the classical divisions of biology no longer correspond to the way in which research is organized and thought develops in biology to-day. The formation of this journal is an attempt to produce some degree of rationalization by bringing together studies of all aspects of development and growth. This is well exemplified by the contents of the first number, which contains articles dealing with the chick embryo, with *Drosophila* larvae, with the ribonucleic acid involved in differentiation of a fern and with the function of SH groups in morphogenesis. In the editorial to the first number the editors say that they are prepared to accept articles written from a wide variety of points of view, for example, analytical or descriptive, technical or theoretical, using either a molecular approach and/or an organismal approach. Micro-organisms, plants and animals are all equally regarded as relevant to the problems of developmental biology.

Native Life in Angola

THE Portuguese Companhia de Diamantes de Angola is noted for the interest it takes in archaeology and the native cultures of the region in which it operates. Business firms are not usually directly concerned with interests of a cultural nature outside their own money-making projects, and this makes it all the more remarkable that the Angola Diamond Mining Co. has published already a large number of splendid volumes, full of illustrations which deal with many aspects of the past and present history of the country. A recent volume (Companhia de Diamantes de Angola (Diamang) Servicos Culturais Dundo-Lunda-Angola Museu do Dundo Publicações Culturais No 37 *Flagrantes da Vida na Lunda* Introdução de José Osório de Oliveira Pp 192 (Lisboa Companhia de Diamantes de Angola 1958)) is a superb publication of large format containing no less than 148 full-page illustrations of the countryside and its inhabitants. We can see basket-makers at work, fishing scenes, a moment in a divination ceremony, a Lunda chief with his robes and ceremonial insignia, etc. The first 44 pages are devoted to an introduction by Dr José Osório de Oliveira, there being Portuguese, French, and English versions. An account of some of the cultural activities of the company is given and also of the country and its people. On the last page the author writes "The honour attributed to the leaders of 'Diamang' in having anticipated in Africa

that which the experts convoked by UNESCO counselled is nothing more than justice, for one cannot fail to look upon the company as the keystone of local native life." This is true, and furthermore, both archaeologists and anthropologists all over the world have reason to thank the Company for the Dundo Museum and many other contributions to learning.

Summer Tanager

FOLLOWING a series of depressions and strong westerly winds, an unusual bird was observed on Bardsey Island on September 11, 1958. It was somewhat smaller than a song thrush, olive green above and deep yellow below, with a heavy blunt bill and peculiarly short legs. Subsequent observations suggested that the bird was a summer tanager, *Piranga rubra*, which had not previously been recorded in any European list, the few red feathers on the head and the back suggested that the specimen was a young male. Details of the observation and of the highly successful work carried out at Bardsey Bird and Field Observatory during 1957 are described in the annual report of that Observatory for 1957, which can be obtained from W M Condry, Eglwysfach, Machynlleth, Montgomeryshire.

Chromosome Numbers in *Solidago*

IN further studies of the genus *Solidago*, J R Beaudry and D L Chabot (*Canad J Bot*, 37, No 2, 1959) have observed the chromosome numbers in 25 taxa of the genus. In all, the chromosome numbers of 42 taxa have now been published. The basic number of the genus is nine. Thirty-three taxa are diploid ($2n = 18$), five are tetraploid ($2n = 36$), three are aggregate taxa containing both diploid and tetraploid cytodesmes, and one is hexaploid ($2n = 54$). Polyploidy has thus contributed to the evolution of the genus *Solidago* but it seems that most of the species have differentiated gradually. *S. decemflora* DC of western North America differs from *S. nemoralis* Ait of the same continent by morphological characters, its geographical distribution, and its chromosome number, the first taxon being tetraploid and the second diploid, the two are thus good species and not merely varieties of the same species. *S. rigida* is considered to be an aggregate, consisting of two entities which are distinguished not only by their morphology and geographical distribution but also by their chromosome numbers, the eastern one (*S. rigida* L.) is tetraploid, whereas the western one (*S. parvirigida* Beaudry) is diploid. The bog and marsh goldenrods, *S. Purshii* and *S. uliginosa*, also possess different chromosome numbers, the first being diploid and the second tetraploid.

Soil Fungi in the Belgian Congo

J MEYER has given a comprehensive account of soil and litter fungi in the Belgian Congo (region of Yangambi) (Publications de l'Institut National pour l'Étude Agronomique du Congo Belge Série Scientifique, No 75 "Moississures du Sol et des Litières de la Région de Yangambi (Congo Belge)", par J Meyer Pp 211+4 planches Bruxelles Institut National pour l'Étude Agronomique du Congo Belge, 1959 190 Belgian francs). In this work, the author has recorded his taxonomic observations on the very considerable number of fungi observed or isolated, leaving the questions of sociology, synecology, etc., to be dealt with later. The generally

accepted classification of soil fungi into native or cosmopolitan species, and exotic fungi (soil myadara), is followed, but the author notes that the exotic organisms require further sub division into two groups namely preferant species (*espèces préférentes*) implying having precedence or priority, and exclusive species. The nature of the vegetation, and the fruits, leaves and branches which fall from it to form the litter, carrying down air borne organisms by which they have become infected, influences the nature of the exotic fungal flora. So also do rhizosphere relationships. Hence the author considers that the work of the soil mycologist must necessarily suffer limitations if it fails to take into account the nature of the vegetation and its litter that is to say, properly envisaged, the phenomenon to be investigated is that of vegetation-litter-soil. In this initial study, some 251 species are listed described and many of them illustrated. Of these 101 came from the soil (13 Phycomycetes, 31 Ascomycetes, and 147 Deuteromycetes) and 60 were observed directly on debris. The Hyphomycetes have been classified according to Hughes's system (1953).

Precambrian Geology of South western Australia

THE Precambrian geology of south western Australia has recently been reviewed by A. F. Wilson (*J. Roy. Soc. Western Australia* 41 57 1958), who provides a new tectonic geological map of a quarter of a million square miles of this region on a scale of 20 miles to the inch. This is the first attempt to integrate all known trends of granites, gneisses and 'greenstones' and on the map these and charnockitic rocks are distinguished for the first time. The well known north north westerly trend of the Goldfield area is found to extend in a general way throughout much of the region. The strike of the granites conforms to the regional strike of the metamorphic rocks but magmatic emplacement is suggested locally. Granitization contacts are also common and filter press differentiation phenomena are known. Geochemical and petrographic features suggest that many gneisses are similar in composition to grey wacke rocks, but that the granites would need to have been subject to some kind of metasomatism to have been produced from such a source. Charnockitic rocks are found over a very large area and seem to have developed in at least four different ways and in two main periods—one early and the other late Archaean. It would appear from radioactive age determinations that the bulk of south western Australia is of early Archaean age and that a late Archaean period of metamorphism has affected parts of the south and south-east, and also possibly the western margin of the shield which is down faulted beneath the Perth basin.

Perkin Centenary Trust Awards

THE Perkin Centenary Fellowship has been awarded to Mr. Brian Whitear, a research chemist in the laboratories of Messrs. ICI Ltd. Mr. Whitear will work at the University of Southampton, under the supervision of Prof. R. C. Cookson, on photochemical reactions of coloured substances. Perkin Centenary Scholarships have been awarded to the following: Mr. Ronald R. Cox (tenable at the University of Birmingham), Mr. B. T. Lawton (tenable at the Royal Technical College, Salford); and to Mr. D. J. Pearson (tenable at the Bradford Institute of Technology).

University News

Hull

THE annual report 1957-58, of the University of Hull notes the establishment of the grade of senior lectureship, to which eight lecturers have been promoted and also another large deficit on the halls of residence. Residence fees have been assessed to provide a surplus, and if costs do not rise appreciably an overall deficit should be avoided during the next three years. The first stage of the new library building is expected to be completed in the summer of 1959 and a provisional building programme of an estimated capital cost of £204,000 has been approved by the University Grants Committee for the years 1960-63 including a new physics building, a hall of residence on the University site, an arts and social science building, and extensions to Ferens Hall. The completed programme will cost nearly £2 million and will provide places in Hull for about half the 2,000 students expected in the University in the 60s. The Senate's report includes brief notes on research work in progress, an account of the work of the Department of Adult Education and a list of publications during the year arranged under departmental headings.

Announcements

H.R.H. THE DUKE OF EDINBURGH has accepted an invitation to become the first Honorary Fellow of the Illuminating Engineering Society.

PROF. J. H. MATTHEWSON, of the Institution of Transportation and Traffic Engineering, University of California, will give two lectures at the Road Research Laboratory, Langley Hall, Langley, Slough Bucks., on 'Experiments on Automobile Collisions' (September 9) and 'A Simulator for Research on Driver Behaviour' (September 16). Both lectures will commence at 3.30 p.m. Tickets can be obtained (free) on application to the Director of Road Research, Road Research Laboratory, Harmondsworth West Drayton, Middlesex.

SIR JAMES DENBY ROBERTS has been appointed chairman of the Joint Committee of the Agricultural and Medical Research Councils and the Development Commission on Biological (Non Medical) Problems of Nuclear Physics in succession to Lord Rothschild, who retired earlier this year. This Committee was formed to sponsor and co-ordinate research on the effects of radioactive substances on plants and animals, and is responsible for the supervision of monitoring fall-out in foodstuffs and other biological materials. Sir James is chairman of the Scottish Society for Research in Plant Breeding and is particularly interested in farming in the Highlands.

IT is announced that the Commonwealth Scientific and Industrial Research Organization (Australia) has formed a new Division of Mineral Chemistry, replacing the Minerals Utilization Section of the Organization's Chemical Research Laboratories. The Division's research under the leadership of Mr. R. G. Thomas will be concerned with the chemical transformation of minerals into a wide variety of useful products.

A COLOURED wall-chart illustrating in section the Metro-Vickers Type EM6 electron microscope has recently been produced primarily for the use of technical colleges and teaching institutions. Supplies have been reserved for lecturers and science teachers and requests for copies should be addressed to the Publicity Department of Metropolitan Vickers Electrical Co. Ltd. Manchester.

INDUSTRIAL RESEARCH ASSOCIATIONS IN BRITAIN

RESearch for Industry, 1958", which reports on work done by the industrial research associations in the Government scheme, this year adopts a new pattern which has much to commend it. It includes the report of the Industrial Grants Committee of the Council for Scientific and Industrial Research which comprises a review of grant policy during 1957-64 (see p. 211 of this issue), and a review of the achievements during the past five years of the ten research associations to which new or revised terms of grant were recommended during the year. Apart from brief notes on any outstanding features of the work of other research associations during the period, the bulk of the report comprises a list of existing associations, giving their officers, total income and publications during the year and a brief note on the scope of the present work of each association. There is also an assessment by Dr D. T. A. Townend of the place of the research associations in the evolution of scientific endeavour, and a report entitled "New Ideas, New Products, New Processes" on how co-operation research serves the textile industries. In this report, which covers the work of several research associations, the point is made that one-fifth of an association's resources is only adequate for fundamental research if the total resources are big enough.

Of the research associations which received new or revised terms of grant during the year, stress is laid on the basic research into the composition of gelatin and glue, the structure of the gelatin molecule, the properties of solutions and gels and the conversion of collagen into gelatin being carried out by the British Gelatine and Glue Research Association, the economic value of the work of the British Hat and Allied Felt Makers' Research Association, the achievements of the British Hydromechanics Research Association in the design and utilization of pumps and in high-pressure hydraulic machinery and in hydraulic model testing. The Furniture Development

Council has conducted a basic investigation into factors affecting the strength and rigidity of cabinet construction, developed test methods for furniture lacquers and worked on a new, economical material—wood chipboard. The Heating and Ventilating Research Council began its first major research project in 1956-57—an investigation of problems arising from the intermittent heating of buildings, with the view of ascertaining possible fuel savings by choosing in advance equipment and programme of the daily heating cycle in relation to the thermal characteristics of the building and installation. The Lace Research Association has carried out much work on new types of yarn and on problems arising in dyeing and dressing synthetic fibre materials, and is engaged in a basic study of the bobbin and carriage, which is the central feature of major types of lace machines.

Basic research carried out by the British Flour-Millers' Research Association includes a complete analysis of the amino-acid composition of flour and of the changes which occur when it is made into bread. The Research Association of British Rubber Manufacturers has extended its cover to plastics, notably polyvinyl chloride and polyethylene, and has been investigating the basic physical characteristics of rubber and plastics and the influence of service conditions such as temperature on these characteristics. An outstanding piece of chemical research increased knowledge of how traces of certain metals, notably copper and manganese, can cause premature deterioration of important classes of rubber products, especially rubber-proofed fabrics. The British Coke Research Association has developed instruments such as an isothermal bomb calorimeter for accurate determination of the calorific value of solid and liquid fuels and an electromagnetic semi-microbalance for use in fundamental studies relating to carbon.

AGRICULTURAL RESEARCH IN BRITAIN

ACORRESPONDENT, commenting in a Scottish farming paper on the Report of the Agricultural Research Council for 1957-58, complained that he could find no reference to research on grass tetany. Because of its current seriousness, he felt that some of the four million pounds that the Council administers should be allocated directly towards research into this problem. If he had read the report with deeper understanding he would have realized that such a criticism was not really justified. For example, at the Rowett Research Institute there are in progress fundamental studies on the physiology of rumen digestion with particular reference to young grass which is high in potash and nitrogen. The work is not labelled grass tetany or hypomagnesaemia, but it is in fact just the sort of work that will lead to a better understanding of the metabolic diseases of livestock which are still very largely unsolved. Agricultural research has long since passed from its old phase of an empirical approach to outstanding problems, and this is well illustrated by this report,

for the main emphasis is on fundamental studies necessary for a better understanding of the vital mechanisms of plants and animals.

Another illustration of this approach is provided by the investigations, mainly at Rothamsted Experimental Station and at the University of Durham, into the biology of the potato root eelworm. Studies have been made of diffusate from potato roots which stimulates hatching of the cysts, and investigations are proceeding at several centres into the chemistry of this material, with the view of obtaining a means of causing hatching in the absence of the host plant.

A feature of the report is the very considerable emphasis which is given to the several aspects of poultry research, which for a number of years was something of a Cinderella so far as the Council was concerned. The industry, with an annual output of £200 millions, is second in importance in Britain to dairying, and it also is one of the most heavily subsidized. It is very important that the industry

should be more efficient, and especially is this true in respect of disease control for wastage is a very heavy source of loss. To day there are two poultry research institutes, one wholly and the other partly financed by the Council, while there is a considerable amount of poultry research being supported at other centres. One pleasing aspect of the breeding work is the attention that is being given to methods which will be within the compass of the small breeder, who is in imminent danger of being squeezed out by the large organizations producing hybrid chickens.

Possibly the most notable advance from the point of view of the farmer relates to the control of husk in cattle, which is caused by the lungworm *Dictyocaulus viviparus*. This work has been undertaken by the University of Glasgow Veterinary School and was started in 1952. The successful outcome of this work is that double vaccination, using doses of larvae that have been partially inactivated by irradiation with X rays gives an effective field control of a disease which has been a serious source of loss to farmers. The cost to the cattle industry has not been confined to deaths and loss of thrift but has included also the

cost of housing and hand feeding susceptible animals in order to avoid infection. Now that farmers have an effective control of the disease, it will be possible for them to put calves out to pasture and thereby considerably lower the cost of rearing. X irradiation opens up enormous possibilities in the control of other endo-parasitic infections and further work is proceeding on this side.

One final point about the Council's activities—though the greater part of its funds go to research institutes such as Rothamsted Experimental Station and the National Institute for Research in Dairying the universities are by no means neglected. Apart from a number of research units there were ninety-four separate projects at sixteen universities which were receiving grants in March 1958. It seems that fears expressed a few years ago that the big institutes would monopolize research in agriculture and the sciences basic to agriculture are groundless, for it is obviously the Council's policy to encourage workers at the universities who have, among their other duties, the task of training research workers to staff the institutes.

SELF-REGULATION IN LIVING SYSTEMS

THE first Ottawa symposium on self regulation in living systems, held in October 1958 (see *Nature*, 183, 730; 1959), led to requests for a second meeting with particular emphasis on problems of stability in self regulating systems. This meeting was held at the National Research Council laboratories in Ottawa on March 11. As on the previous occasion a very wide range of professions was represented, and the attempt was made to increase our understanding of the behaviour of living systems by analogy with known physical and mathematical techniques and concepts.

The opening paper outlining the nature of the problem, was by a physiologist, Dr A. S. V. Burgin (McGill University, Montreal). Burgin emphasized that all physiological problems are multifactorial in character, and that in a real biological system it is impossible to isolate a single variable. A real need exists for more adequate mathematical techniques to deal with such problems. However, at present simplifying assumptions are essential in order to reduce problems to manageable form. Thus we may, for example, consider the blood circulatory system as made up of two pumps—namely, the right and left ventricles of the heart—connected in series with each other and with the blood vessels of the body. The problem here is how the outputs of the two pumps are maintained equal to one another. It is found that over a wide range of input pressures the output flow is proportional to this pressure, and in this way automatic regulation is achieved. It appears that blood pressure is controlled by sensors acting via the base of the brain to cause dilation or contraction of capillaries in the circulatory system. In these cases, and, for example, in the problem of maintenance of body temperature, the mechanisms by which the actual operating values are determined remain largely unknown at present. It was also pointed out that there are definite time cycles within the body for which at present no explanations have been given. Following Burgin's paper there was considerable discussion as to whether the dependence

on temperature of the rate of chemical processes might provide an adequate mechanism for the maintenance of an internal temperature standard.

Dr A. C. Smith (Computing Centre, University of Ottawa) presented some analysis of the properties of idealized control systems, using the method of the Laplace transformation. The analysis, however, was limited to strictly linear systems, and it was felt that the non linear problem is in fact of great importance to physiologists and others. The conclusion reached in the analysis was that optimum control conditions obtain when the control action depends upon both the variable under control and its time derivative. This conclusion agreed with the general experimental observations of the physiologists present. In the discussion the influence of time delay or phase of negative feedback on the stability of systems was of primary interest. Physiological systems discussed in this connexion included problems of neurological instability and the recent work, reported in the literature, on the relation between stammering and delays in the reception of aural signals. The galvanometer amplifier using a light beam and photocell to provide a high degree of negative feedback offers a simple mechanical system showing some of the important features. If the time delay in the response of the cell is appreciable the galvanometer amplifier system may build up to a state of oscillatory instability. It should be emphasized that the polarity of the feedback is still nominally negative if the feedback is connected up in the opposite sense (positive feedback) then the galvanometer amplifier becomes entirely unstable, and obviously so!

An outline of some modes of operation of digital computers by Dr Bradford Dunham (Research Laboratory, International Business Machines Corporation, New York) opened the way for analogies to be drawn with living systems. In programming a computer a specific problem must be given a precise mathematical formulation and then translated into machine language. Under these conditions

say that the machine will either perform activities requiring no 'judgment', or it may be adapted to include activities requiring 'judgment' provided that the programme contains some means for evaluating consequences. We can then go further and consider problems which are rather inexact, or poorly defined, with the condition that the answer(s) to the problem (which may be very difficult to find) must be easy to check or recognize as correct when arrived at. In order to do this, the machine changes its own programme in some successive manner and at the same time evaluates the effect of these changes. It certainly appears that this technique of 'machine search' can be regarded as a learning process (perhaps even more ?) in that the machine itself attempts to arrive at the correct way to tackle a problem.

Dr F L McNaughton (Montreal Neurological Institute) made some remarks on stability in relation to the human system, pointing out first that we are still far from an adequate understanding of how the brain works. Experiments in which people were isolated from their environment result in hallucinations in the experimental subject and some distortion of perception when the period of isolation is ended, a clear interdependence of nervous system and environment is indicated. When this adjustment of man to his environment breaks down he shows the symptoms of disease. Broadly speaking, it appears that only damage or disease in the general receptor or motor areas of the brain produce immediately identifiable external symptoms. Considerable parts of other areas of the brain may be removed or quite drastic surgery carried out, with what appear to be only transient after-effects in many cases. In discussion, the close analogy between the apparent organization of the human brain and the problem of 'machine search', mentioned above, was pointed out. It has been found that in machine 'learning' of this

type, the initial and final stages of the programme (which might perhaps be likened to 'receptor and motor areas') are critical in the solution of the problem, but otherwise many alternative programmes appear to be possible.

Dr G Glinski (Department of Electrical Engineering, University of Ottawa) spoke on the general problem of stability and adaptability of multi-loop feedback control systems. Systems of this type are much closer to living systems than the simpler control systems discussed earlier since a number of variables are involved in controlling a single output. In addition, there may be feedback to one or more inputs and it is also possible to take into consideration some interaction between input variables.

In the previous symposium, Dr A C Burton (University of Western Ontario) presented some demonstrations on the significance of visual perception. The present symposium concluded with a short demonstration by Dr Burton of interaction between visual inputs. This followed an experiment first performed by Mach in which an interaction between neighbouring receptors in the eye leading to a sharpening of the contrast between light and dark regions is shown quite dramatically by the apparent presence of intensified dark and light bands in the penumbra region of a straight edge when projected on to a lantern screen.

Following the meeting, a panel discussion took place on the Canadian Broadcasting Corporation system under the chairmanship of Sir Robert Watson-Watt, in which Drs Burgen, Dunham and MacDonald took part. During this spontaneous discussion the significance of 'learning' by machines was explored further. It is probable that a further symposium will be held—perhaps this time in Montreal.

D K C MACDONALD
DOUGLAS L MARTIN

THERMONUCLEAR PROCESSES

A CONVENTION on "Thermonuclear Processes" was held in the Great Hall of the Institution of Civil Engineers on April 29-30. The convention was organized by the Institution of Electrical Engineers in conjunction with the British Nuclear Energy Conference. A total of twenty-two papers were read, half of which were concerned exclusively with the engineering problems arising out of research into controlled thermonuclear reactions. The remaining papers were largely re-statements of results given at the Geneva Conference on the Peaceful Uses of Atomic Energy last year, albeit presented in a form more suitable for a predominantly engineering audience. However, some new results were given, particularly in the papers submitted by the United States and the U S S R.

The mechanism of energy loss remains the outstanding question in connexion with the toroidal stabilized pinch or *Zeta*-type discharge. At the Geneva Conference, Dr S A Colgate of the University of California claimed that the entire energy loss during the first 7-8 μsec of the discharge life-time in his small torus was due to runaway electrons with an energy of about 2 keV striking the walls. Later, Drs Hughes and Kaufmann of Associated Electrical Industries, Ltd, Aldermaston, published results obtained with the *Sceptre* apparatus showing that

impurity ions were drifting around the torus with the unexpectedly high velocity of 10^8 cm/sec. The angular momentum of the deuterium plasma deduced from these measurements was in agreement with the notion of runaway electrons as the chief source of loss. This happy unanimity was destroyed by the release of two further results during questions at the Convention. First, a search had been made on *Zeta* for the Doppler shift in impurity spectra indicating drift motion and none had been found. Secondly, the group at Los Alamos under Dr J A Phillips working with *Perhapsatron S4* had some evidence to show that the whole of the energy loss from their torus was due to radiation in the vacuum ultra-violet region. Clearly more work will have to be done before the problem is finally resolved.

Mr G B F Niblett of the Atomic Weapons Research Establishment, Aldermaston, described some new experiments on the rapid compression of plasma. In this work a fast-rising axial magnetic field is created inside a linear discharge tube by means of a long single-turn copper coil coupled to a condenser bank. The resulting ring discharge ionizes the gas and is rapidly collapsed by the rising magnetic pressure. The heating principle is the same as that of the fast linear pinch first reported by Kurchatov at Harwell in 1956, but the changed geometry avoids

electrode effects and is expected to be hydromagnetic ally more stable. A ringing discharge with a frequency of about 200 kc/s was produced in a $1\frac{1}{2}$ in bore tube. A rotating mirror photograph of the discharge in nitrogen showed successive contractions of the discharge corresponding to the oscillations of the coil current. In other measurements, the radial oscillation of the hollow cylindrical shell of plasma when confined between two magnetic fields was observed. It was suggested that these oscillations might be used to heat the plasma.

A paper presented by Mr. J. D. Jukes of the Atomic Energy Research Establishment, Harwell, analysed a system for extracting electrical energy directly from any fusion reactor which uses the principle of magnetic confinement. To extract the energy the plasma is taken through a compression cycle by varying the confining magnetic field. During the compressed state, energy accumulates in the plasma due to the heating of the nuclear fuel. When expanded the plasma temperature is low so that fusion reactions occur infrequently and the plasma cools, losing energy by bremsstrahlung radiation. In this way, waste heat is removed from the plasma and a closed Carnot cycle can be achieved. Since the neutrons produced in the fusion reactions are unaffected by the magnetic field, only the energy released in charged particles can be extracted in this way. Mr. Jukes concluded that it should be possible to withdraw about one third of the available energy from proposed fusion devices directly as electrical energy.

Dr. C. M. van Atta of the University of California Radiation Laboratory presented a survey of the very large American programme in this field which costs 40 million dollars a year and employs three hundred professional staff. A new experiment demonstrating the propagation of torsional Alfvén waves through plasma was described. To produce the plasma a linear discharge carrying a current of 20 k amp in an axial magnetic field of 10 kilogauss is used. The waves are generated by applying an alternating radial electric field between one of the electrodes and the conducting wall of the tube. The measured velocity of propagation increases linearly with the axial magnetic field strength and is in close agreement with theory if the ion density is assumed to correspond to all the gas initially in the tube being ionized. This work is being done by Dr. J. Wilcox at the Radiation Laboratory, Berkeley. Among other experiments reported in this paper were hydrodynamic stability studies by Dr. S. A. Colgate using high current pulses through sodium, and similar studies by Dr. H. P. Furth using plasma and a variety of magnetic field configurations.

An important consideration in the magnetic mirror method of confinement is the accuracy of the assumption that the magnetic moment of a spiralling charged particle is a constant. The principle of mirror confinement is based on the adiabatic invariance, and since a confined particle may undergo many millions of reflexions from the mirrors during its containment, the accuracy required is of a high order. In experiments by Dr. E. Lauer of Berkeley, positrons with energies of the order 1 MeV resulting from the β decay of radioactive neon were shown to be contained between magnetic mirrors for 10^4 reflexions. The distance between the mirrors was 1 m and the Larmor radius of the electrons 0 cm.

Dr. I. N. Golovin of the Institute of Atomic Energy, Moscow gave an account of research into magnetic mirror systems in the Soviet Union. He

described an experiment on the adiabatic invariance of the magnetic moment similar in principle to that reported by Dr. van Atta. In this case electrons from the radioactive decay of tritium were used and confinement for up to 10^4 reflexions had been demonstrated. Work had also been done to find the effect of azimuthal asymmetries in the magnetic field on the number of reflexions. It was found that until the azimuthal variations in the magnetic field strength exceeded about 10 per cent there was no effect on this containment. The remainder of Dr. Golovin's paper was devoted to a discussion of the work on *Ogra*, the large Russian mirror machine. He stated that *Ogra* was built to study plasma instabilities and was designed to produce a hot plasma with a density of 10^{12} ions/cm³ if no instabilities were encountered. The principle of injection in this machine is that of dissociation of the input beam of 200 keV molecular ions through collisions with the residual neutral gas in the volume. By balancing the favourable process of dissociation against the unfavourable one of charge exchange, it can be shown that a dense plasma will only be formed if the input beam current exceeds a certain value, the so-called burn out current. The burn-out current for *Ogra* was calculated assuming that the background neutral gas density was determined by the ionization of neutral gas by fast ions and by the release of neutral gas from the walls through the impact of fast particles. A figure of the order 200 m amp was obtained for the formation of a hydrogen plasma. Another assumption in the calculation was that the path length of an injected molecular ion moving in the magnetic field and failing to make a collision should be not less than 10^4 cm before it returns to the injector. This length depends critically on the magnetic field configuration and the ion gun alignment, and one of the first tasks with the machine will be to optimize these. A very low initial pressure is also required and to date the lowest value achieved has been $\sim 3 \times 10^{-6}$ mm mercury. In view of the size of the vacuum chamber, 1.5 m bore and 20 m long, this represents a considerable technical achievement. The present ion source gives 150 m amp of molecular ions at 100 keV. Up to the moment only a 30 m amp beam of ions has been injected into the machine and the burn out condition has not been achieved. Impressive photographs were shown of the beam spiralling in the magnetic field.

During question time Dr. K. W. Allen of the Atomic Weapons Research Establishment, Aldermaston, raised the subject of the order of magnitude difference in the relevant charge exchange cross sections as measured by Fedorenko in the U.S.S.R. and by Barnett in the United States. Replving, both Dr. van Atta and Dr. Golovin declared their faith in the measurements carried out in their respective countries, but Dr. van Atta hoped that the work would soon be repeated in a third and preferably neutral country. Other points raised during discussion periods concerned the importance of the spectral region 10 Å–400 Å for plasma measurements, the power lost by synchrotron radiation from the electrons in a magnetically confined plasma and the need for more work on surface bombardment effects.

Finally, Sir George Thomson called for more refined experiments, with purer plasma and more homogeneous magnetic fields. He concluded by declaring his faith in the ultimate solution of the problem of obtaining economic power from fusion reactions.

R. BICKFORTH

BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION

NEW RESEARCH LABORATORIES

ON May 13 Sir Alexander Fleck, chairman of Imperial Chemical Industries, Ltd., opened a new laboratory block for the British Non-Ferrous Metals Research Association at Euston Street in London. The laboratories have gradually been extending on this site since 1930 and now contain about 53,000 sq ft of floor space and house a staff of about 180. They serve the needs for co-operative research of practically all branches of the non-ferrous metals industry, and the 40-50 research projects in progress cover the production, properties and uses of the commoner non-ferrous metals, certain aspects of the metallurgy of the metals concerned with nuclear energy, and metal finishing.

The new laboratory was made possible by the generous response to a building fund on the part of the Association's membership of more than 600 firms and of the Department of Scientific and Industrial Research, which has treated contributions as grant earning. The main features of the new block are a much-enlarged foundry, new corrosion and physics laboratories and a new electroplating shop. Alterations to existing buildings have enabled a new creep testing laboratory to be built which will allow the capacity to be doubled to more than 100 units, the rehousing of many different types of fatigue testing machines in one room, and the provision of more space for the General Metallurgy Section. This, among other things, gives the Section more room for vacuum apparatus for the determination of gases in metals.

In the foundry, moulds are now made in one well-equipped bay and poured in an adjacent melting and casting shop. The melting equipment consists of five gas-fired lift-out crucible furnaces, a gas-fired bale-out furnace for research into die-casting problems, a 600-lb low-frequency induction furnace for studying the performance of refractory linings, and also an electric resistance furnace and a high-frequency furnace each capable of melting charges of up to 20 lb of copper or nickel alloys in vacuum or special atmospheres.

From the inception of the laboratories the value of physical methods of analysis has been realized and the Association's work in developing spectrographic analysis of metals to its present state of efficiency is well known. Recently, the X-ray fluorescence method of analysis has aroused considerable interest and it appears extremely promising for analysing the major constituents in alloys and for the analysis of ores and slags. Its potentialities are being studied, using a spectrometer designed by the Physics Section and built in the Association's workshops. In the Chemistry Section emphasis is on the physico-chemical methods of analysis, including polarography, spectrophotometry and the use of the flame spectrophotometer.

The Physics Section has two X-ray diffraction sets and a variety of special-purpose cameras for crystal orientation studies, the identification of phases in compounds and other tasks. An electron diffraction camera is available for studying oxide and other thin films on metal surfaces.

Instrumentation for automatic inspection and process control is becoming increasingly important in

the metal industry, and several studies are being made of problems in this field. They include the use of eddy currents for rapid inspection of tubes and rods for flaws, an investigation into emissivity variations of hot metal surfaces which affect the performance of radiation pyrometers, and the development of a novel thermo-electric gauge for measuring, non-destructively, the thickness of electro-deposits.

Research on electroplating and allied metal-finishing processes is now housed in a large new laboratory equipped both for fundamental work and for plating on a semi-industrial scale in pilot plating lines. Equipment is available for measuring the stresses during plating, for measuring cathode potentials and throwing power, and for assessing the ductility and adhesion of coatings. Exposure tests on plated specimens are carried out on the roof of the laboratories, but much work has been done on accelerated corrosion tests, including one in which the parts are exposed to a humid atmosphere containing traces of sulphur dioxide which simulates in a few hours the effects of exposing the parts to a city atmosphere for several months.

Many modern plating solutions contain organic additions which affect the smoothness, brightness and mechanical properties of the coatings in a beneficial way. Exactly how these organic agents do this is not known, and typical addition agents prepared with tracers, such as carbon-14 and sulphur-35, are being used to study the mechanism of the process.

In the Corrosion Section one laboratory is employed solely for sea-water corrosion studies, the current work being concerned mainly with the attack on heat-exchanger tubes handling heavily polluted estuarine waters in power stations, oil refineries and in ships. Some of these tests are at controlled potentials to simulate the effects of applied cathodic protection. The influence of marine atmospheres is assessed by exposure at a site on Hayling Island and the laboratory roof site is used mainly for inland tests. Stress corrosion tests are carried out at both these sites and there is also a special high-humidity room for this purpose in the corrosion laboratory.

One of the main uses of non-ferrous metals is the handling of supply waters, and the effect of water composition on the resistance to corrosion of various metals is being studied at field stations and also in the laboratories using synthesized waters.

The General Metallurgy Section, besides carrying out the usual metallographic work, heat treatment and constitutional studies, contains a metal-working shop with a 12-in rolling mill, a 500-ton press for extrusion and forging, a small forging hammer and a drawbench. This section of the laboratories is also working on the development of titanium, zirconium and thorium alloys and has argon arc melting equipment appropriate for this type of work. Special apparatus which uses an atmosphere of argon for carrying out long-term creep tests on these reactive metals is housed in the new creep laboratory.

HIGHER EDUCATION IN EAST AFRICA

IN 1954, a delegation, headed by Dr (now Sir) Eric Ashby, was appointed to assist in planning the development of Makerere College, Uganda. In addition to indicating the general scope of the development which it thought appropriate, the delegation also made reference to the broad problem of developing higher education in East Africa as a whole. As a result, a working party, under the chairmanship of Sir Alexander Carr Saunders, visited East Africa in July 1955, to review in greater detail the requirements of higher education. Its findings were published in a White Paper¹, in which the Governments of Kenya, Tanganyika, Uganda and Zanzibar fully accepted the desirability of further university college development, within the scope of a single University of East Africa.

A second working party, under the leadership of Dr J. F. Lockwood, visited East Africa in July 1958 to examine proposals for the creation of new institutions of higher education in particular within the framework of a University of East Africa.

Its report², recently published, contains four main recommendations, which are being considered by the East African Governments. (1) By re-organization and extension, the Royal Technical College of East Africa, in Nairobi, should, without delay, become a university college of a new type in which academic and professional courses of equal standing would have their place with Faculties of Science, Arts, Engineering and Special Professional Studies. (2) That plans should be formed for the establishment of an inter-territorial university college in Tanganyika at Morogoro, to be opened in 1956-57, or as soon thereafter as possible. (3) That a university of East Africa should be created by 1960 and that the university colleges then existing and any which may be founded thereafter, should be associated as constituent colleges of the university. (4) Since the carrying out of these recommendations will guarantee adequate provision for higher technological and professional training for some years ahead, no additional institutions offering facilities for these kinds of training should at present be contemplated.

If these recommendations are accepted the new University of East Africa would have as its constituent colleges, Makerere College, the Royal College of East Africa (the reorganized Royal Technical College) and the new university college in Tanganyika. The report adds: "The inter-racial character of the colleges we take for granted as an indispensable element in their fully liberal nature and outlook. That they should also be wholly inter-territorial was likely for many years to be a vital necessity in terms both of academic need and of finance."

It is suggested that since the college in Nairobi would begin its career as a university college under the same system which now applies to Makerere College, students of the reconstructed college would work for degrees of the University of London, under a scheme of special relationship. The University of East Africa, following its foundation, would grant its own degrees, for which students of all the colleges would read. Since the university college in Tanganyika would probably not begin its teaching until after 1958, students of this college would at the outset, read for degrees of the newly established university.

Though realizing that its proposals are modest the working party stresses that the cost, in terms both of capital and recurrent expenditure, will be high and points out that the several Governments will be unlikely to be able to meet capital expenditure from their own joint resources. "The compulsion of their present circumstances will thus force them to lean heavily on expectations of generous grants from Colonial Development and Welfare funds."

The report concludes with the hope that financial help will be forthcoming, for the individual colleges from non-official sources and pays tribute to generous gifts, which the Gandhi Memorial Academy Society has made to the Royal Technical College.

GLOEOSPORIUM IN APPLE STEM WOUNDS

TWO contributions on *Gloeosporium* in apple stem wounds have recently appeared (*J. Hort. Sci.*, 32, No. 2 1959). R. O. Sharples has reported on an investigation of the response of apple stems to wound infections by the fungus *Gloeosporium perennans*. In anatomical studies relating to the establishment of infections on apple branches he has shown that the defensive mechanism of the host includes the production of suberized barriers by bark phellogens and the blocking of xylem vessels by gum deposition. These responses follow wounding, whether or not the wounds are inoculated with *G. perennans*, but the presence of the fungus delays the response. Accordingly the size and form of lesion induced by inoculation are largely determined by the effect of the fungus in postponing the normal wound healing process.

This effect, and consequently penetration by the pathogen is greatest during the period of host dormancy. Invasion occurs most rapidly through the sieve tubes and the vessels and fibres of the outer xylem, the longitudinal intercellular spread of hyphae through the cortex is slower.

Intra-cellular infection of the pith and medullary ray cells occurs in pruning wound infections. When the progress of the infection is arrested, the phellogen and cambium lay down barriers of callus tissue consisting of parenchymatous outer cells surrounding a core of wound wood. After the lesion has been thus isolated the fungus persists as a saprophyte and eventually forms acervuli on the exposed dead host tissue. A limited spread of infection past the suberized barriers occasionally appears.

BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION

NEW RESEARCH LABORATORIES

ON May 13 Sir Alexander Fleck, chairman of Imperial Chemical Industries, Ltd., opened a new laboratory block for the British Non-Ferrous Metals Research Association at Euston Street in London. The laboratories have gradually been extending on this site since 1930 and now contain about 53,000 sq ft of floor space and house a staff of about 180. permanent mysteries to some, unable to learn the conventions of each idiom or keep standard comparisons in their heads. The aggregation of many individual values into composite ecological statistics offers no problem to modern computing devices, which also are capable of mapping electronically information fed into them by some scanning apparatus in an aeroplane.

Airborne radar, duplicated perhaps with magnetometers and gravimeters, adds to the sensitivity and completeness of the record. Not only images but also radio waves, power points and carbon dioxide can be 'photographed'. Infra red photography picks up besides the aeroplane on the airfield the heat of the runway and thus the number of planes recently started. The emphasis in modern photogrammetry has thus shifted from the static physical condition to the recordable human transactions.

In brief, there are three chief ways in which such a survey can be used:

(1) To supply general social and economic statistics such as the presence and growth of industry, agriculture, house building, road improvements, conservation and productivity, cross checked with ground social surveys and nationally or regionally collected annual or census statistics.

(3) The planning of policy and of improvements and services is based on these surveys. A deft handling of photographic material should be combined with opinion studies and other studies on the ground such as traffic and migration counts done by mechanical or human agents.

(3) The evaluation of policy, that is, the effectiveness of any constructive activity. This will probably be done increasingly as part of ordinary photogrammetric work, with the help of someone competent in statistics and sociology and with a knowledge of the particular part of the world that is to be studied. At a later stage perhaps, when many different studies have been accumulated and compared, the skilled social interpreter may also be able to make useful deductions from a study of the photographs unaided by ground studies.

EMISSION OF RELATIVELY HIGH-ENERGY IONS FROM LOW-VOLTAGE ARCS

By E. R. HARRISON

Atomic Energy Research Establishment, Harwell, Berks

SOME interesting effects have been observed with low voltage arcs for which so far no completely satisfactory explanations have been found. The principal effect observed is the emission of luminous rays consisting of ions of the cathode material at energies much greater than the total potential difference across the arc.

In the experiments described below, the arc is formed between a tungsten, molybdenum or tantalum filament, which is separately heated, and a nickel anode at a distance of about 5 cm and is maintained in a rare gas, usually argon, at a pressure of 1–50 mm mercury. The applied potential difference is 40–80 V and the current is 200–500 mA. The arc is thermally constricted or 'punched' to a diameter of approximately 5 mm. In arcs of this kind the electrons, ions and gas molecules are in an approximate thermal equilibrium at a temperature generally of the order of 10^4 °C. The ionization potentials of tungsten, molybdenum and tantalum are lower than the excitation potentials of the rare gases and in the present experiments the arcs therefore tend to consist of ions formed from metal volatilized from the cathode. Spectroscopic analysis of the arc reveals strong W II and W I (Mo II and Mo I) lines but only a few faint argon lines.

The first effect observed is that tungsten is deposited at the point where the arc makes contact with a cool nickel anode. This deposition occurs even when the anode is screened from any material evaporated directly from the hot cathode. The rate of deposition on the anode, as determined by activation analysis, is typically 3×10^{-4} gm/sec amp^{-1} , equivalent to a tungsten ion current of 1.5 mA in an arc of 1 amp. It appears that in hot cathode-cool anode arcs of this type there is an efficient mechanism for

transporting positive ions from the cathode to the anode against the electric field. It is evident that such a transport mechanism is required if the ions in the arc are formed originally from volatilized cathode material in the immediate vicinity of the cathode.

A second effect is observed when the arc is constricted by a small aperture of $\frac{1}{2}$ –1 mm diameter in a nickel diaphragm placed between the cathode and anode as shown in Fig. 1. The cathode is now about 5 cm from the aperture diaphragm, and the anode is about 10–20 cm, or preferentially, the anode has a coaxial aperture of 2–3 mm diameter and is spaced about 5 mm from the first aperture as is shown in Fig. 1. On the anode side of the apparatus the pressure is maintained within the range of 10^{-1} to 10^{-2} mm mercury. As a result of the constriction, impressive luminous white rays are observed projecting from the centre of the small aperture into the low pressure region. Occasionally the rays form a uniform diverging beam as in Fig. 2 but more often

Fig. 1. Apparatus for producing a constricted arc which ejects energetic positive ions through the aperture anode.

Fig 2 Positive tungsten ion rays of approximately 450 eV accelerated by an argon arc of 250 m amp and 80 V

the beam is divided into several individual rays of small diameter which flicker and move in synchronism with the instability motion of the arc. Spectroscopic analysis of the deposit formed by the rays incident on a receiving target shows that the rays consist of tungsten atoms. On changing the cathode material to molybdenum, the deposit formed by the rays is found to consist only of molybdenum, but the luminosity of the rays is unaltered and their colour only very slightly affected.

Electrostatic and magnetic deflexion experiments establish the surprising fact that the rays are positively charged and have energies greater than the potential difference across the arc. The accelerated ions are reasonably monoenergetic and have an energy in the range 100–750 eV, depending on the conditions of the arc. With an aperture reduced to $\frac{1}{2}$ mm diameter and a pressure of 80 mm mercury in the arc, tungsten ion rays with energies greater than 1,000 eV have been observed with a potential difference of only 60 V across an arc of 500 m amp. Rays may also be observed when the pressure is as low as 1 mm mercury, in this case the arc develops only in a limited region adjacent to the aperture in a form reminiscent of a 'ball of fire'. The rays are not so easy to produce when the supporting gas is either helium or neon, possibly because the arc currents in these experiments are limited to relatively small values. With krypton and xenon the rays are produced as readily as in the case of argon.

Difficulty is encountered when attempts are made to measure electrically the current in the tungsten ion rays, not only because of secondary electrons but also because there is apparently an electron flux which is not easily eliminated. Activation analyses of deposits formed by the rays incident on a target show that in a typical case there is a total flux of 0.4×10^{-6} gm/sec $^{-1}$ amp $^{-1}$ equivalent to 0.2 m amp in an arc of 1 amp. This is consistent with the fact that a large fraction of the tungsten migrating towards the anode is deposited around the aperture. More intense fluxes, up to 1 m amp per ampere of arc current, can be achieved by applying an alternating potential difference of 20–50 V between the cathode and an enclosing cylindrical electrode. The flux and luminous intensities do not appear to be critically dependent upon the frequency in the range 10^4 to 10^7 c/s, and it is possible that the increase in intensity is due to the enhanced fluctuation movements induced in the arc.

Potential fluctuations of up to 20 V of the electrodes and movable probes have frequencies of 10^4 – 10^5 c/s with a wide spectrum of 'hash' superimposed. The fluctuations in luminosity of the rays as detected by a photomultiplier are similar to those of the arc and reveal frequencies in the same range as the potential variations. The emission spectrum of the

rays is predominantly W II, or in the case of a molybdenum cathode, Mo II.

A third effect observed is that the rays frequently show a pronounced variation in intensity of luminosity along their length. Thus, if the rays are projected into a region of low pressure of 10^{-3} mm mercury, in a typical case all rays are bright for the first 2.5 cm, the luminosity then becomes faint for about 0.5 cm, and then abruptly increases in intensity and thereafter diminishes slowly up to distances as great as 30 cm.

A completely satisfactory explanation has not been found for all the effects described. The luminosity of the rays is most probably due to charge exchange between the tungsten (molybdenum or tantalum) ions and the supporting gas, the abrupt variations in the luminosity, however, are not understood. The mechanism responsible for producing the positive anode rays is most probably associated in some way with the transport of ions in the arc from the cathode to the anode. The oscillatory or 'hashy' nature of the arc may be an essential self-sustaining feature. Thus, sound waves will be propagated with a phase velocity of $(\gamma k T/m)^{1/2}$, where m is the mass of the atoms of the supporting gas, and one possibility is that the electric fields produced by the separation of the electrons and ions are sufficiently large to cause a fraction of the ions to move with a drift velocity of approximately $(e \lambda E \sin \phi / m)^{1/2}$ in phase with the sound waves, where λ is their mean free path, E is the oscillatory electric field, and ϕ is the phase angle. Experiments designed to detect the propagation of signals along the arc at the phase velocity of sound have not been entirely successful, and the evidence is meagre and unconvincing. Possibly the arc is in a turbulent state, and generates and propagates sound waves only over small distances.

If disturbances of approximately 1 mm wavelength are propagated in the arc, the potential fluctuations suggest that the associated electric fields are of the order of 400 V cm $^{-1}$. In the region of the constriction the oscillatory electric field might be expected to increase inversely as the diameter of the arc, giving a value of 6×10^3 V cm $^{-1}$ if allowance is made for the fact that the arc is smaller than the constricting aperture. It is therefore possible that the ions gain their energy of several hundred electron volts from the oscillatory electric fields in the constricted region of the arc.

Energetic ions of several hundred electron volts have been observed elsewhere⁶ in high-current, low-pressure arcs in magnetic fields used in the DCX experiments. However, the arc conditions are considerably different and the accelerating mechanism is not necessarily of the same kind as that proposed above.

Acknowledgments are made to Mr J D Lawson, Prof A von Engels, Dr P C Thonemann and Dr S A Ramsden for their suggestions and interest, to Mr D H F Atkins for the activation analyses and to Mr F T Burks for the spectroscopic analyses of the ray deposits.

TEICHOIC ACIDS FROM BACTERIAL WALLS

FROM THE DEPARTMENT OF CHEMISTRY, KING'S COLLEGE (UNIVERSITY OF DURHAM)
NEWCASTLE UPON TYNEComposition of Teichoic Acids from
a Number of Bacterial Walls

INVESTIGATIONS on the function of the nucleotides cytidine diphosphate glycerol¹ and cytidine diphosphate ribitol² led to the discovery of a new group of natural polymers, the teichoic acids, in the walls of certain bacteria³. In *Bacillus subtilis* the teichoic acid is of the type shown in formula (1), whereas that in *Staphylococcus aureus* has the related structure (2), in which the sugar component is glucosamine. That from *Lactobacillus arabinosus* is of the type (1), but some of the ribitol residues bear two glucosyl substituents, whereas others are unsubstituted by glucose. A more detailed discussion of their structure and relationship with cytidine diphosphate ribitol has been given elsewhere⁴.

We had intended to confine the term teichoic acid to those polymers of ribitol phosphate of the general structure (1) or (2) found in bacterial walls. A more extended survey of other organisms (see Table 1) has shown that some bacteria contain a new type of teichoic acid in which ribitol has been replaced by glycerol. Preliminary studies on the hydrolysis of these glycerol derivatives by acids, or by alkali followed by prostato phosphatase, show that they have the structure (3). Visual chromatographic estimation indicates that they represent more than 30 per cent of the wall in some cases. Consequently, the restricted nomenclature originally adopted must now be modified to include all polymers of the types (1), (2) and (3).

The polyol phosphate derivatives in walls of *L. arabinosus* and *B. subtilis* are clearly ribitol teichoic acids of the type (1), and no trace of a glycerophosphate polymer has been detected in these walls. All strains of *Staph. aureus* examined so far contain a ribitol teichoic acid (2) but these walls also contain other traces or in one case a considerable amount of a glycerophosphate polymer. Similarly walls of *Streptococcus faecalis* contain a ribitol teichoic acid of the type (1) and a glycerophosphate polymer.

It is interesting that *L. casei*, *L. delbrückii*, *L. bulgaricus*, *Staph. albus* and *Staph. citreus*, unlike the other lactobacilli and staphylococci examined so far contain glycerol teichoic acid but no trace of a ribitol teichoic acid. The compound from *Staph. albus* and *Staph. citreus* was present in their walls but preparations from whole cells were used for the work on the three lactobacilli and it is not known whether the teichoic acid in these preparations originated from the walls. The compound from *L. casei* is of the type (3) in which alanine is attached to a polymer of glycerophosphate. The amount of hexose in preparations of this material is very small and we have been unable to demonstrate any glycosylglycerol linkages. It seems likely that all the glycerol-teichoic acids in the bacteria listed will be of type (3) but the presence of glycosyl residues is still possible in some cases.

In addition to the organisms discussed here a number of others yielded small amounts of glycerophosphate on acid hydrolysis of their walls. There is evidence that polyols other than ribitol and glycerol are present together with these in teichoic acid preparations from some organisms, and sugars other than glucose or glucosamine may occur.

Extracts prepared from whole cells of all organisms examined contained a glycerophosphate polymer even when no such polymer was present in the isolated walls. It is not known whether this is a teichoic acid of type (3) which has been lost from the walls during their preparation or whether it is associated with other cell structures.

In contrast to the variations in polyol and sugar the only amino acid found in purified preparations of teichoic acid is alanine. This amino acid isolated from teichoic acid from *L. arabinosus* and *Staph. aureus* has the D configuration⁴. It was shown earlier that the alanyl residues are in ester linkage and it is now found that the lability of these residues (half life 5 min at 37°, pH 7.2, 1.1 M hydroxylamine) in neutral salt free hydroxylamine solution is comparable to that of amino acids bound to ribonucleic acid (half life 3 min. at 30°, pH 7.2, 0.8 M hydroxylamine)⁵. The alanine ester linkages are therefore much more reactive than normal amino acid esters which do not react significantly with hydroxylamine under comparable conditions⁷.

Fig 1 Micrograph showing a late stage in the formation of a residual body. E, endoplasmic reticulum, L, lipoidal body, M, mitochondrion, RNA, aggregate of particles containing ribonucleic acid ($\times c 7,300$)

in spermatid development all the above-mentioned inclusions had concentrated within a small lobe of cytoplasm near the base of the nucleus. Just before the mature spermatid is shed, this lobe of cytoplasm is cast off and becomes spheroidal in shape. The spheroidal bodies which arise in this way clearly correspond to the residual bodies of Regaud. Each residual body is bounded by a membrane derived from the cell membrane of the corresponding mature spermatid. Within, and close to, the limiting membrane lie two or three small groups of granular mitochondria, several lipoidal bodies (sometimes arranged in crescent fashion) and Golgi remnant. The greater part of each residual body is occupied by a comparatively large, eccentrically placed mass of strongly basophilic material.

Soon after the sperms have been shed the residual bodies migrate peripherally. As precisely as could be determined by light microscopy, this appeared to be due to phagocytosis by Sertoli cells. Afterwards, the residual bodies come to lie close to Sertoli nuclei at the border of the tubule.

Changes occur within the residual bodies both during their peripheral migration and while they are at the periphery of the tubule. The first sign of these changes is the appearance of minute vesicles about 0.3μ in diameter which form along the edges of the basophilic material. During their movement towards the periphery the residual bodies become reduced in size, their diameter decreasing from about 10μ to 5μ . Finally, there is a loss in basophilia and then all that can be seen is the limiting membrane, some mitochondria and lipoidal bodies, and the Golgi remnant. After this stage it is impossible to identify the residual bodies with any certainty. However, accompanying and following upon the 'end' stage, lipoidal bodies of about the same size as the residual bodies, and in the same general location, appear within the Sertoli cells. We have studied the residual bodies at this time to see if they become converted into the lipoidal bodies described above. What may be transitional stages have, in fact, been observed, but only very rarely.

Histochemical tests have shown that the basophilic material referred

to above consists of, or contains, ribonucleic acid. The lipoidal bodies which occur within spermatid cytoplasm, and form part of the residual bodies, do not respond positively to Baker's⁵ acid haematin test for phospholipins nor to Schultz's⁶ test for cholesterol. The same negative responses for both tests are also given by the lipoidal bodies within Sertoli cells.

Electron Microscope Observations

Tissue was fixed in 1 per cent osmium tetroxide buffered to pH 7.3⁷. It was then embedded in a 1:3 mixture of *n*-methyl and *n*-butyl methacrylate, sectioned with a glass knife and examined in a

Siemens Elmiskop Ia. Due to the comparatively small size of the residual bodies and the fact that they occur only under certain physiological conditions a great deal of material has had to be examined to find even the more important stages referred to above.

Observations made by electron microscopy are in accord with those made by light microscopy. In addition, finer details have been seen. During late formative stages (Fig 1) the mitochondria are irregular in shape and characteristically cluster around a local concentration of endoplasmic reticulum. Adjacent to these elements is a group of osmiophilic granules which correspond to the lipoidal bodies seen under the light microscope. The Golgi remnant consists of a few paired membranes in parallel arrangement and aggregates of many small vesicles enclosed by two or more membranes. Near the inclusions just described occur one or two particulate masses, spheroidal in general outline and corresponding to the ribonucleic acid granules seen by light microscopy. At a later stage in the formation of the residual bodies the mitochondria are either greatly elongated and constricted in the middle (as though in a process of division) or are small, dense and spheroidal. The endoplasmic reticulum appears to consist of membranes delimiting vacuoles of various sizes. The basophilic material consists of one large mass of fine particles.

Studies by electron microscopy have confirmed quite definitely that the residual bodies are phago-

Fig 2 Micrograph showing residual bodies within Sertoli cells at the border of a tubule. Some of the residual bodies (RB) are comparatively intact. Others have been largely absorbed and appear irregular in shape (RB'). P, primary spermatocyte, S, Sertoli cell ($\times c 7,300$)

cytosed by the Sertoli cells. Within any one Sertoli cell, even in ultra thin sections, we have observed up to six residual bodies. Each residual body is enclosed by a variable number (1-4) of fine membranes. When the body reaches the edge of the tubule the limiting membranes are no longer continuous. Residual bodies at the periphery contain the same basic constituents as those seen in the last stages of their formation in the tubulo lumen. Later, the basic phallic material and various other components are absorbed until all that remains is an irregular-shaped body which is intensely osmophilic and presumably lipidal (Fig. 2). About this time a peripheral ring of lipid can be demonstrated in Sertoli cells by the use of appropriate light microscopical techniques.

When the residual bodies come to lie close to the Sertoli nuclei (adjacent to the tubule tissue) changes occur both within the Sertoli cytoplasm and in germ cells. Within the Sertoli cells appears the peripheral ring of lipid mentioned above. Mitochondria either increase in number or become concentrated peri-

pherally. The cytoplasmic matrix (as seen under the electron microscope) becomes very dense. The young spermatids start to elongate and become more deeply enclosed by Sertoli cytoplasm. There is an increase in chromatin content of the nuclei of type B spermatogonia. It is possible that the residual bodies produce in the Sertoli cells some influence that may serve to trigger off the changes in the germ cells as reported above. The residual bodies would then be responsible for the local control of spermatogenesis. This is now being investigated further.

We are grateful to the Wellcome Trust for a grant to purchase an electron microscope and to St Bartholomew's Hospital and Medical College for further financial help.

GROWTH RESPONSES TO SELENIUM IN LAMBS

By DR. J. W. McLEAN, G. G. THOMSON and J. H. CLAXTON

Canterbury Agricultural College Christchurch New Zealand

UNTIL recently, selenium as a dietary constituent was regarded as of significance only when it occurred in excess of certain well-defined limits. In selenium poisoning areas about 5 p.p.m. in herbage is considered to be the tolerance limit for livestock¹. It has now been shown²⁻⁴ that selenium in organic and inorganic form has high protective powers against necrotic liver degeneration in the rat and mouse, and exudative diathesis in the chick fed basal diets deficient in vitamin E and containing a high proportion of *Torula yeast*, protection being obtained respectively with 0.04 p.p.m. and 0.1 p.p.m. of selenium in the ration. It has been shown also in the chick that selenium is a required nutrient necessary for normal growth as well as for the prevention of exudative diathesis⁵.

So far as large animals are concerned there is evidence to indicate that sodium selenate fed to pregnant ewes at the rate of 0.1 p.p.m. of selenium in the ration will protect their lambs against muscular dystrophy (white muscle disease)⁶.

Furthermore trials conducted in the South Island of New Zealand⁷ suggest a protective action of selenium when given to the lambs themselves, in naturally occurring outbreaks of a type of muscular dystrophy affecting young lambs.

Arising from the idea that subclinical muscular dystrophy might be one of the factors responsible for the slow growth rate of weaned and unweaned lambs commonly observed in the South Island—a condition known locally as 'ill thrift'—we commenced trials to investigate the possible effects of selenium supplements on the growth rate of various classes of lambs on the College farms. This communication records the observations made to date.

All lambs were individually identified with ear tags, divided at random into treatment and control groups and weighed at intervals of 2-3 weeks. Selenium was given as sodium selenate by subcutaneous injection in sterile water at the rate of 1.0 i.u.m.

selenium every 7-10 days. Lambing commenced about the beginning of August and weaning occurred in the first week of December.

The first three trials involved pure bred Romney, Border Leicester and Corriedale ram and ewe lambs reared on the College home farm. The fourth trial was carried out on Corriedale wether lambs brought on to the College farm from the same farm on which the fifth trial was conducted (Ashley Dene farm).

Mean live weights and gains are set out in Table 1, with the numbers of lambs in each group given in brackets.

Table 1 MEAN LIVE WEIGHTS AND GAINS (lb.)

| Trial 1 | Romneys | 0.10.58 | 22.1.59 | Gain |
|---------|------------------------|------------|---------|-------|
| | Date | 30.5 (94) | 60.4 | 38.0 |
| | Selenium | 31.6 (88) | 60.3 | 34.8 |
| | Control | | | 4.1* |
| | Difference in 105 days | | | |
| Trial 2 | Border Leicesters | 19.10.58 | 22.1.59 | |
| | Date | 51.2 (40) | 79.2 | 28.0 |
| | Selenium | 50.3 (47) | 71.9 | 21.6 |
| | Control | | | 6.4* |
| | Difference in 93 days | | | |
| Trial 3 | Corriedales | 21.11.58 | 22.1.59 | |
| | Date | 46.9 (101) | 63.1 | 16.5 |
| | Selenium | 47.4 (50) | 60.0 | 13.5 |
| | Control | | | 3.0* |
| | Difference in 62 days | | | |
| Trial 4 | Corriedale wethers | 11.11.58 | 19.2.59 | |
| | Date | 52.2 (20) | 74.5 | 22.3 |

| | Control | | | 10.7* |
| | Difference in 91 days | | | |

* Significant at 1.0 per cent level

Analysis of variance shows that the differences in gains in live weight are highly significant ($P < 0.01$) in all trials. The magnitude of these responses varies considerably, being greater in general in the lambs from the Ashley Dene farm. The response is rapid, evidence of increased growth being observable in all groups in 2-3 weeks after treatment commenced.

Further, it appears to be a continuing one, although the duration of some of the trials is obviously short.

Explanation of the mode of action of selenium in producing a growth response under these conditions must at the present time be rather speculative. There can be little doubt now that traces of selenium are required by the animal for normal metabolism, that vitamin E and selenium are interrelated in their metabolic functions, and that vitamin E cannot completely replace the need for selenium. The growth responses in lambs may therefore be taken as an indication of a specific selenium deficiency, one manifestation of which is a slowing up of growth, and another a predisposition to muscular dystrophy and possibly other conditions in which the metabolism of vitamin E is involved.

This concept is in conformity with the known distribution of naturally occurring outbreaks of exudative diathesis in chicks and white muscle disease in lambs¹⁰, both of which, in New Zealand, are almost entirely restricted to the South Island.

In this respect it is of interest to note that the groups of lambs giving the greatest response (trials 4 and 5) came from flocks in which losses from white muscle disease had occurred earlier in the season before these trials commenced (4 out of 600 for trial 4 and 7 out of 51 in trial 5).

At the other extreme, in the pure-bred lambs on the College farm, only one death occurred from white

muscle disease, there were no other signs of the disease in the 580 lambs born this season, nor has there ever been any history of the disease on this farm. Selenium responses have therefore been obtained, not only in lambs from areas where white muscle disease is common, but also where it has been extremely rare.

On the other hand, the College farm has had a history of so-called 'ill-thrift' of varying degrees of severity over the past three years. Just what part, if any, selenium deficiency plays in the 'ill-thrift' syndrome in this area is not as yet clear. That it may be a factor of some importance is indicated by the data presented in these trials.

This is a preliminary report only and final results will be published elsewhere.

CARBOHYDRATE — AMINO-ACID INTER-RELATIONS IN BRAIN CORTEX IN VITRO

By M. M. KINI and PROF. J. H. QUASTEL, F.R.S.

McGill-Montreal General Hospital Research Institute, 3619 University Street, Montreal

IT is now well known that when radioactive glucose is metabolized by brain cortex *in vitro*, radioactive amino-acids are formed¹⁻³. A mince of the brain of one-day old mice when incubated with glucose uniformly labelled with carbon-14 incorporates radioactivity in all amino-acids of brain protein with the exception of threonine¹. Rat brain cortex slices can convert ¹⁴C-glucose into labelled glutamic, aspartic and γ -aminobutyric acids³. When ¹⁴C-glucose is injected intraperitoneally into one-day-old mice, radioactivity is found in aspartic and glutamic acids and in alanine in the brain proteins². It is evident that glucose, during its normal metabolism in the brain, produces intermediates—presumably the α -ketonic acids—that undergo conversion to amino-acids largely at the expense of organic nitrogen already available in the brain cell. Such amino-acids must play a part not only in the various biosynthetic operations of the nerve cell but also in the maintenance of ionic balance in the cell. It is therefore of importance to understand more fully than is known at present the precise relations existing between sugars and amino-acids in the brain, and the manner in which these relations may be affected by substances that influence brain metabolism. Among such substances are potassium ions, which have long been known to exert profound effects on the metabolism of nerve cells. Cationic balance is a factor of fundamental importance for the metabolism of brain, both aerobically⁴ and anaerobically⁵.

We have therefore carried out experiments to ascertain the effects, on the formation of amino-acids from glucose in the brain cortex *in vitro*, of those concentrations of potassium ions that produce optimal stimulation of respiration, of a neurotropic drug such as amytal and of a respiratory inhibitor such as sodium malonate. The experiments have been carried out not only to throw more light on the mode of action of these substances but also to indicate the importance of the consideration of the amino-acids as part of the over-all metabolism of sugars in the nervous system.

The experimental work was carried out with the conventional Warburg manometric apparatus. Slices of rat brain cortex weighing approximately 90 mgm were incubated in a medium of the following composition: sodium chloride, 128 mM, potassium chloride, 5 mM, calcium chloride, 3.6 mM, magnesium sulphate, 1.3 mM, disodium hydrogen phosphate, 10 mM brought to pH 7.4 with N hydrochloric acid. The final volume was 1.0 ml and each flask contained 5 mM glucose uniformly labelled with carbon-14 with an activity of 10⁶ counts/min when counted on aluminium planchets at infinite thinness. 0.1 ml of 20 per cent potassium hydroxide was used as carbon dioxide absorbent. Incubations were carried out in oxygen at 37° C for 1 hr, after which the tissue slices were homogenized in 8.0 ml of 80 per cent ethanol, centrifuged and the supernatant evaporated at 30° C in a current of air. The dried

extract was dissolved in 0.5 ml of water and 400 μ l was chromatographed two-dimensionally on Whatman No 1 paper. The solvents used were *sec* butanol/80 per cent formic acid/water (70:11:17 v/v/v) for the first phase, and phenol/water/ammonia (1 lb phenol:110 ml water:17 ml ammonia spec grav 0.88) for the second phase.

The radioactive spots were localized by radioautography and the radioactivities of the spots were measured quantitatively using a Tracerlab counter with a mica window 28 mm in diameter and thickness 1.5–1.8/cm². Activities were corrected for background. The counting efficiency by this method was calculated to be 10.8 per cent.

All results are expressed as counts per minute for 100 mgm of wet-weight tissue.

Effects of Potassium Ions on Amino-acid Formation from Glucose and Fructose

The stimulating effects of potassium ions at 105 mM (preferably expressed as mEq/litre (milliequivalents/litre)) on brain respiration, shown many years ago by Dickens and Grovillo¹ and by Ashford and Dixon², take place with the identical substrates, glucose, pyruvate or lactate, which permit responses to applied electrical pulses. The potassium effect has many of the metabolic characteristics of brain tissue in the excited state. It is suppressed by low concentrations of narcotics that have no demonstrable effects on the unstimulated respiration in the presence of glucose which is quantitatively the most important metabolic fuel of the brain^{3,4} and of ganglia⁵. The narcotic suppression of potassium stimulation of brain respiration applies not only to central narcotics⁶ but also to local anesthetics⁷, to chlorpromazine, alcohols and aldehydes^{8,9} and to the newer depressants of the glutarimide type, and focuses interest on the mechanism of potassium stimulation of neuronal respiration. This stimulation seems greatly to resemble that brought about by oscillating electrical pulses^{10,11}, which may produce their effects by ionic displacements, for example, of potassium, calcium or sodium. All the evidence points, in fact, to the similarity in many respects of the biochemical effects of electrical stimulation of the brain cortex slices with those due to the presence, in the incubation medium, of potassium ions at 0.1 molar concentration. Brain homogenates or minces are, as is well known, unresponsive to either forms of activation. Presumably in the conscious animal such stimulation operates by the action of sensory impulses, and high sensitivity to narcotics of the metabolic activity of the stimulated brain cell ensues.

The potassium stimulation of brain respiration is highly sensitive to malonate, whereas unstimulated brain respiration is but little affected by malonate^{12,13}. It is evident^{14,15} that potassium ions activate the citric acid cycle involved in glucose oxidation in the brain or a pace making step closely associated with it.

Results showing the effects of the addition of 105 mM potassium chloride solution to the incubation medium on amino-acid formation in rat brain cortex slices are shown in Table 1. It will be seen that in a normal physiological medium containing 5 mM potassium ions there is a labelling of glutamic acid, aspartic acid, glutamine, alanine and γ aminobutyric acid in the presence of glucose and of fructose both uniformly labelled with carbon 14. The labelling of glutamic acid, with both sugars, is highest among the

Table 1 EFFECTS OF 0.1 M POTASSIUM CHLORIDE ON AMINO-ACID PRODUCTION FROM GLUCOSE AND FRUCTOSE UNIFORMLY LABELLED WITH CARBON 14 IN SLICES OF RAT BRAIN CORTEX. Substrate concentration, 5 mM (10⁶ counts/min.). Incubation time, 60 min. temperature 37°C. Amino acids are expressed as counts/min./100 mgm wet tissue/10⁶ counts/min. uniformly labelled substrate per vessel.

| Amino-acid formed | Glucose 1- ¹⁴ C | | Fructose 1- ¹⁴ C | |
|-----------------------------|----------------------------|-----------------------|-----------------------------|-----------------------|
| | 5 mM K ⁺ | 105 mM K ⁺ | 5 mM K ⁺ | 105 mM K ⁺ |
| Glutamic acid | 8 057 \pm 358 | 5 810 \pm 476 | 4 784 \pm 307 | 942 \pm 21 |
| Aspartic acid | 1 318 \pm 164 | 1 183 \pm 185 | 2 150 \pm 122 | 2 127 \pm 101 |
| Glutamine | 1 280 \pm 112 | 2 80 \pm 200 | (9) | (4) |
| Alanine | 057 \pm 60 | 794 \pm 40 | 374 \pm 63 | 224 \pm 24 |
| γ Amino butyric acid | 906 \pm 142 | 1 401 \pm 164 | 730 \pm 22 | 271 \pm 10 |

All values are given with mean standard errors.

* Glutamine could not be counted when fructose was used as substrate as the fructose spot overlapped that of glutamine.

amino-acids investigated aspartic acid showing the next highest activity. It is noteworthy that the labelling of aspartic acid on incubation with uniformly labelled fructose greatly exceeds that of aspartic acid found after incubation with uniformly labelled glucose.

The most important quantitative effect of the presence of 105 mM potassium ions which increases the respiration of brain cortex slices in the presence of glucose by almost 100 per cent, is to bring about a large increase in the labelling of glutamine (nearly 100 per cent) and of γ aminobutyric acid. The total count of the labelled amino-acids in the presence of glucose uniformly labelled with carbon 14 is increased from 9 287 to 11 331 counts/min. The labelling of glutamic acid or alanine is slightly increased whereas that of aspartic acid is slightly decreased.

It may be noted that the ratios of radioactive glutamate:glutamine and γ aminobutyrate found with potassium stimulated rat brain cortex slices in presence of glucose are 1:0.44:0.27 (Table 1), which approximate to the ratios of these amino-acids normally found in the adult rat brain cortex¹⁶, namely, 1:0.43:0.17.

As it is well known that glutamine is derived from glutamate in brain in a reaction involving adenosine triphosphate¹⁷ the process bringing about the removal of free ammonium ions that are liberated during the functional activity of the brain¹⁸, and that γ aminobutyric acid is derived from glutamate by a decarboxylase normally present in the brain¹⁹, we may consider that the net effect of exposing brain cortex slices in presence of glucose, uniformly labelled with carbon 14 to 105 mM potassium ions, is to increase the total yield of glutamic acid, the excess over the normal appearing as both glutamine and γ aminobutyric acid. This phenomenon may be explained by the fact that the presence of 105 mM potassium ions accelerates the operation of the citric acid cycle in the brain, increasing the rate of turnover of intermediates, among which is a keto glutarate which by transamination with intracellular amino-acids, forms glutamate and thence glutamine and γ aminobutyric acid.

Typical results given in Table 2 lead to the conclusion that the presence of potassium ions accelerates the conversion of pyruvate to acetyl-coenzyme A. The results demonstrate that the presence of 105 mM potassium ions greatly increases the rate of oxidation in brain cortex of both pyruvate 1-¹⁴C and pyruvate 2-¹⁴C to carbon 14 dioxide the latter process being much more inhibited by the presence of malonate than the former. The fact that some inhibition

Table 2 COMPARISON OF THE EFFECTS OF 0.01 M SODIUM MALONATE AND 0.1 M POTASSIUM CHLORIDE ON OXIDATION OF PYRUVATE-1-¹⁴C AND PYRUVATE 2-¹⁴C BY SLICES OF RAT BRAIN CORTEX
Substrate concentration, 10 mM (10⁴ counts/min), incubation time, 60 min temperature, 37° C, aerobic Carbon-14 dioxide evolved expressed as counts/min/mgm dry weight tissue/hr [10⁴ counts/min substrate per vessel]

| Experimental conditions | Pyruvate 1- ¹⁴ C | | Pyruvate 2- ¹⁴ C | |
|--|-----------------------------|-----------------------|-----------------------------|-----------------------|
| | 5 mM K ⁺ | 105 mM K ⁺ | 5 mM K ⁺ | 105 mM K ⁺ |
| Sodium pyruvate only | 1,166 | 2,008 | 481 | 1,040 |
| Sodium pyruvate + 0.01 M sodium malonate | 903 | 1,342 | 258 | 330 |

of the former process by malonate occurs leads to the conclusion that part of the carbon-14 dioxide derived from pyruvate-1-¹⁴C is formed after its fixation and metabolism by the citric acid cycle

Granting that the effect of the presence of 105 mM potassium ions is an increased rate of formation of acetyl-coenzyme A, it becomes at once apparent (see Fig. 1) that the rate of formation of α -ketoglutarate (and thereby the rates of formation of glutamate, glutamine and γ -aminobutyrate) should be increased, whereas that of oxalacetate (and thereby aspartate) may not be increased, as its greater rate of formation is balanced by its greater rate of removal by condensation with the increased quantity of acetyl-coenzyme A that has become available

Fig 1

The conclusion that the major effect of increased potassium ions is to increase the velocity of formation of acetyl-coenzyme A from pyruvate in brain cortex makes it possible to understand the mode of action of potassium ions in affecting the formation of amino-acids from fructose uniformly labelled with carbon-14. It will be seen, in the results quoted in Table 1, that in the presence of the normal potassium ion concentration (5 mM), there is a marked increase of labelled aspartate and a marked decrease of labelled alanine as compared with the amounts of these amino-acids formed in the presence of glucose uniformly labelled with carbon-14. When the potassium ion concentration is increased to 105 mM, the outstanding effects are the large falls in the amounts of labelled glutamate and γ -aminobutyric acid. Owing to experimental difficulties, when using fructose on paper chromatograms, it was not possible to make accurate assays of the radioactive glutamine formed

The significant factor to be taken into account in interpreting the results found with uniformly labelled fructose (Table 1) is the much lower affinity of fructose for brain hexokinase than that of glucose.²⁴ The result of this lower affinity is a diminished availability of pyruvate in the brain cortex slices, under the experimental conditions quoted, a fact that accounts for the feeble anaerobic glycolysis exhibited by brain cortex in presence of fructose. Sufficient pyruvate is available, however, to enable the citric acid cycle to operate and to yield a respiratory value of the same order as shown by glucose in presence of brain cortex. The lack of availability of pyruvate, apart from that amount required for the citric acid cycle to operate, is also shown by the much lower ability of brain cortex slices to form lactic acid or to synthesize acetyl choline in presence of fructose as compared with that found in the presence of glucose.²⁵ Although respiratory activities, and presumably, therefore, the amounts of available adenosine triphosphate, of brain cortex slices in the presence of glucose and fructose are approximately the same, the rate of formation of acetyl-coenzyme A in the presence of the former sugar is greater than in the presence of the latter

The lowered availability of pyruvate, in brain cortex slices in the presence of fructose uniformly labelled with carbon-14, results in there being less acetyl-coenzyme A available for condensation with oxalacetic acid formed during the operation of the citric acid cycle. This in turn leads to more oxalacetic acid being available for transamination into aspartic acid than occurs with glucose. On this interpretation, the larger yields of labelled aspartic acid found in the presence of uniformly labelled fructose than in the presence of uniformly labelled glucose is directly due to lack of available acetyl-coenzyme A for the acetylation of oxalacetic acid. The lowered availability of pyruvic acid from uniformly labelled fructose is shown also by the diminished rate of formation of labelled alanine (Table 1) in the presence of this sugar

The effects of an increased concentration of potassium ions on amino-acid formation from fructose may also be understood. The acceleration of conversion of pyruvate to acetyl-coenzyme A by the presence of 105 mM potassium ions leads to an increased rate of respiration, so that more of the limited pyruvate available is converted to carbon dioxide. There is therefore less pyruvate available for conversion to amino-acids. Experiment shows (Table 1) that a total count of 8,056 counts/min for the amino-acids investigated falls to 3,564 counts/min in the presence of 105 mM potassium ions

The limited amount of pyruvate, made available from fructose, leads ultimately to the formation of a smaller quantity of α -ketoglutarate than takes place with glucose, in spite of the increased rate of formation of acetyl-coenzyme A due to the presence of 105 mM potassium ions. This in turn leads to smaller amounts, at equilibrium, of labelled glutamate and γ -aminobutyrate. The quantity of labelled aspartate formed, however, remains approximately constant. This occurs, presumably, because the malic acid enzyme that transforms pyruvate to malate with fixation of carbon dioxide, and thence to oxalacetate and aspartate, is operating optimally. This process is already known to occur with retina²⁶ and with mouse brain²⁰

It is therefore possible to obtain an understanding of the relations existing between glucose or fructose,

and the amino acids derived from these sugars in the brain, both in the presence of normal and high concentrations of potassium ions, on the basis of our present knowledge of the operations of the citric acid cycle in brain of transaminating processes affecting the α ketonic acids, and on the conclusion that the stimulating action of potassium is largely directed to the conversion of pyruvate into acetyl coenzyme A.

The implications of these findings are considerable for they indicate that cationic balance, by influencing the relative velocities of the neurochemical processes affects the formation of substances such as acetyl choline or γ aminobutyric acid, which are now well known to be implicated in the electrophysiology of the nervous system.

Effects of Sodium Malonate on Glucose-Amino-Acid Inter-relations

In the presence of 10 mM sodium malonate the respiration of brain cortex stimulated by potassium is inhibited to the level of the endogenous respiration, which is only slightly affected.

The effects of the addition of 10 mM sodium malonate on the formation of labelled amino acids from glucose uniformly labelled with carbon 14 are shown in Table 3.

Table 3. INFLUENCE OF 0.01 M SODIUM MALONATE ON AMINO-ACID FORMATION FROM GLUCOSE UNIFORMLY LABELLED WITH CARBON 14 WITH AND WITHOUT 0.1 M POTASSIUM CHLORIDE. Experimental conditions as in Table 1. Results (counts/min./100 mgm wet tissue/10⁵ counts/min. glucose) are the mean values of three sets of experimental results.

| Amino-acid formed | 5 mM K ⁺ + 0.01 M malonate | 10 mM K ⁺ + 0.01 M malonate |
|-----------------------------|---------------------------------------|--|
| Glutamic acid | 1390 | 995 |
| Aspartic acid | 359 | 533 |
| Glutamine | 301 | 72 |
| Alanine | 133 | 60 |
| γ -Aminobutyric acid | 532 | 194 |

The most noteworthy effect of the malonate is the decrease in labelling of all the amino acids: a total amino acid count of 9,287 counts/min. is reduced by malonate to 3,334 counts/min. The percentage decrease effected by malonate is greater in the presence of 105 mM potassium ions. The total count of 11,381 counts/min found with the high potassium ion concentration is reduced to 1,904 counts/min when the malonate is added. Thus not only is the potassium stimulation of brain respiration abolished by malonate¹² but also its stimulation of amino acid labelling in the presence of radioactive glucose. The suppression of respiration is reflected by the lowered availability of pyruvate and hence in the diminished production of labelled alanine and of α ketoglutarate and hence in the diminished rates of formation of glutamate, glutamine and γ -aminobutyric acid.

Effects of Sodium Amytal on Amino-acid Formation from Glucose

In accordance with the conclusion by Michaelis and Quastel¹³ that a narcotic, such as chloralhydrate suppresses specifically at low concentrations the activity of a process playing an intermediate part in tissue respiration between a flavoprotein involving diphosphopyridine nucleotide and cytochrome oxidase it has been shown¹⁴ that amytal (5-ethyl 5-isoamyl barbiturate) is a highly effective inhibitor of the oxidation of reduced diphosphopyridine nucleotide and its associated phosphorylations.

An effect, therefore of the addition of a narcotic, such as amytal, to respiring tissue is to bring about an increase in the ratio of reduced diphosphopyridine nucleotide to diphosphopyridine nucleotide in the cell. The change in this ratio or the diminished availability of diphosphopyridine nucleotide for its various linked reactions in cell metabolism has a variety of consequences. One obvious result is an increase in the rate of reduction of pyruvate, derived from aerobic breakdown of glucose in the brain cell to lactate, so that an increased aerobic glycolysis in the presence of the narcotic takes place. This is a well known phenomenon.¹⁵ Other results due both to the changed velocities of the diphosphopyridine nucleotide linked reactions and to the diminished availability of adenosine triphosphate consequent upon the suppression of oxidation of reduced diphosphopyridine nucleotide may be expected to take place.

The effects of the addition of 0.5 mM sodium amytal on amino acids formed from glucose uniformly labelled with carbon 14, in the presence and absence of 105 mM potassium ions are shown in Table 4. At this concentration amytal exerts only a small inhibitory effect on the oxidation of glucose by the unstimulated brain cortex slices but almost a complete suppression of the potassium stimulated respiration of brain cortex in the presence of glucose.¹⁶ The results (Table 4) demonstrate these effects.

Table 4. INFLUENCE OF 0.5 mM SODIUM AMYTAL ON AMINO-ACID FORMATION FROM GLUCOSE UNIFORMLY LABELLED WITH CARBON 14 WITH AND WITHOUT 0.1 M POTASSIUM CHLORIDE. Experimental conditions as in Table 1.

| Amino-acid formed | 5 mM K ⁺ + glucose-U- ¹⁴ C 0.5 mM amytal | 105 mM K ⁺ + glucose-U- ¹⁴ C 0.5 mM amytal |
|-----------------------------|---|---|
| Glutamic acid | 5703 \pm 335 | 6761 \pm 450 |
| Aspartic acid | 1002 \pm 55 | 601 \pm 51 |
| Glutamine | 1095 \pm 80 | 111 \pm 10 |
| Alanine | 1104 \pm 70 | 856 \pm 36 |
| γ -Aminobutyric acid | 1793 \pm 45 | 1470 \pm 123 |

(a) In normal physiological media (5 mM potassium ions) the presence of 0.5 mM amytal produces a marked increase in the rates of formation of labelled γ -aminobutyric acid and alanine, with relatively small changes in the rates of appearance of labelled glutamate, aspartate and glutamine.

(b) In the presence of 105 mM potassium ions and 0.5 mM amytal there is a very large fall in the rate of formation of labelled glutamine from 2,397 counts/min. (Table 1) to 111 counts/min. (Table 4). There is a fall also in the rate of formation of labelled alanine and aspartic acid and also in that of glutamic acid.

The results may be explained in the following manner.

(1) With the unstimulated slice of brain cortex the amytal brings about a diminution of available diphosphopyridine nucleotide, so that less pyruvate is oxidized to acetyl-coenzyme A and less α ketoglutarate is converted to succinate. There is not only, therefore, an increased rate of conversion of pyruvate to lactate but also an increased rate of conversion, by transamination, of labelled pyruvate to alanine and of labelled α ketoglutarate to glutamate. The latter reaction is reflected in an increased rate of formation of labelled γ -aminobutyrate. The rate of formation of glutamine is not increased; it is in fact decreased, presumably because the suppression of oxidation of reduced diphosphopyridine nucleotide leading to a diminished synthesis of adenosine tri-

phosphate, results in a diminished amount of the latter being available for synthesis of glutamine

(2) With the stimulated slices of brain cortex, in which the oxidation of pyruvate by diphosphopyridine nucleotide to acetyl-coenzyme A is greatly enhanced, the effect of the presence of the narcotic is to suppress this oxidation owing to the lowered availability of diphosphopyridine nucleotide. The increase of reduced diphosphopyridine nucleotide leads to an increased rate of formation of lactate (that is, increased aerobic glycolysis), this process taking place partly at the expense of pyruvate that would otherwise be transformed to alanine. A similar suppression of oxidation of α -ketoglutarate leads to enhanced labelling of glutamate. The synthesis, however, of glutamine from glutamate is almost entirely blocked by the narcotic, by its suppression of synthesis of adenosine triphosphate normally coupled with the oxidation of reduced diphosphopyridine nucleotide.

It is evident that the processes controlling glucose - amino-acid inter-relations in both the unstimulated and stimulated slice of brain cortex and in the absence or presence of a narcotic such as amytal may be interpreted satisfactorily on the basis of the conclusions that the stimulation consists of an acceleration of the conversion of pyruvate to acetyl-coenzyme A and that the narcotic brings about a suppression of endogenous oxidation of diphosphopyridine nucleotide by cytochrome oxidase and its associated phosphorylations.

Summary

(1) Glucose and fructose, both uniformly labelled with carbon-14, in the presence of slices of rat brain cortex, are partly converted to radioactive glutamic acid, glutamine, γ -aminobutyric acid, aspartic acid and alanine. The yields, and relative proportions, of these amino-acids found with the uniformly labelled glucose differ considerably from those found with uniformly labelled fructose. An outstanding difference is the large yield of labelled aspartic acid found with fructose as compared with that from glucose.

(2) When brain cortex respiration in the presence of glucose or fructose is stimulated by the addition of 105 mM potassium ions, large changes take place in the yields and relative proportions of radioactive amino-acids. With glucose, the effect is greatly to increase the yield of glutamine and γ -aminobutyric acid. With fructose, the effect is greatly to diminish the yield of labelled glutamate.

(3) It is concluded, from the effects of the addition of 105 mM potassium ions on the formation of carbon-14 dioxide from pyruvate-1-¹⁴C and pyruvate-2-¹⁴C, and on the relative inhibitory effects of malonate on these processes, that the stimulating effect of addition of potassium ions on the respiration of brain cortex is largely directed to an acceleration of a pace-making step, the conversion of pyruvate to acetyl-coenzyme A.

(4) The presence of malonate, which abolishes the potassium ion stimulation of respiration of brain cortex, brings about a greatly diminished labelling of all amino-acids derived from glucose, uniformly labelled with carbon-14, and in the presence of added potassium ions almost completely blocks the formation of alanine, glutamine, and γ -aminobutyric acid.

These results can be satisfactorily explained on the basis of the conclusions that the amino acids are derived from glucose by transamination of the α -ketonic acids derived during the operation of the citric acid cycle and that the potassium ion stimula-

tion of the metabolism of brain cortex is due to its acceleration of the oxidation of pyruvate to acetyl-coenzyme A.

(5) The presence of the narcotic, 0.5 mM sodium amytal, produces, with the unstimulated brain cortex slice, a marked increase in the yield from glucose uniformly labelled with carbon-14, of labelled γ -aminobutyric acid and alanine, with relatively small changes in the yields of labelled glutamate, aspartate and glutamine. With the stimulated brain cortex slice (that is, with 105 mM potassium ions) the narcotic at small concentrations brings about a very large fall in the yield of labelled glutamine, falls in the yields of labelled alanine and aspartic acid and a rise in the yield of labelled glutamic acid. These results may be adequately explained on the basis of the conclusions given above, together with the conclusion that the main effect of the narcotic is to suppress the oxidation of reduced diphosphopyridine nucleotide by cytochrome oxidase and its associated phosphorylations.

phosphate, results in a diminished amount of the latter being available for synthesis of glutamine

(2) With the stimulated slices of brain cortex, in which the oxidation of pyruvate by diphosphopyridine nucleotide to acetyl-coenzyme A is greatly enhanced, the effect of the presence of the narcotic is to suppress this oxidation owing to the lowered availability of diphosphopyridine nucleotide. The increase of reduced diphosphopyridine nucleotide leads to an increased rate of formation of lactate (that is, increased aerobic glycolysis), this process taking place partly at the expense of pyruvate that would otherwise be transformed to alanine. A similar suppression of oxidation of α -ketoglutarate leads to enhanced labelling of glutamate. The synthesis, however, of glutamine from glutamate is almost entirely blocked by the narcotic, by its suppression of synthesis of adenosine triphosphate normally coupled with the oxidation of reduced diphosphopyridine nucleotide.

It is evident that the processes controlling glucose-amino-acid inter-relations in both the unstimulated and stimulated slice of brain cortex and in the absence or presence of a narcotic such as amytal may be interpreted satisfactorily on the basis of the conclusions that the stimulation consists of an acceleration of the conversion of pyruvate to acetyl-coenzyme A and that the narcotic brings about a suppression of endogenous oxidation of diphosphopyridine nucleotide by cytochrome oxidase and its associated phosphorylations.

Summary

(1) Glucose and fructose, both uniformly labelled with carbon-14, in the presence of slices of rat brain cortex, are partly converted to radioactive glutamic acid, glutamine, γ -aminobutyric acid, aspartic acid and alanine. The yields, and relative proportions, of these amino-acids found with the uniformly labelled glucose differ considerably from those found with uniformly labelled fructose. An outstanding difference is the large yield of labelled aspartic acid found with fructose as compared with that from glucose.

(2) When brain cortex respiration in the presence of glucose or fructose is stimulated by the addition of 105 mM potassium ions, large changes take place in the yields and relative proportions of radioactive amino-acids. With glucose, the effect is greatly to increase the yield of glutamine and γ -aminobutyric acid. With fructose, the effect is greatly to diminish the yield of labelled glutamate.

(3) It is concluded, from the effects of the addition of 105 mM potassium ions on the formation of carbon-14 dioxide from pyruvate-1- ^{14}C and pyruvate-2- ^{14}C , and on the relative inhibitory effects of malonate on these processes, that the stimulating effect of addition of potassium ions on the respiration of brain cortex is largely directed to an acceleration of a pace-making step, the conversion of pyruvate to acetyl-coenzyme A.

(4) The presence of malonate, which abolishes the potassium ion stimulation of respiration of brain cortex, brings about a greatly diminished labelling of all amino acids derived from glucose, uniformly labelled with carbon-14, and in the presence of added potassium ions almost completely blocks the formation of alanine, glutamine, and γ -aminobutyric acid.

These results can be satisfactorily explained on the basis of the conclusions that the amino-acids are derived from glucose by transamination of the α -ketonic acids derived during the operation of the citric acid cycle and that the potassium ion stimula-

tion of the metabolism of brain cortex is due to its acceleration of the oxidation of pyruvate to acetyl-coenzyme A.

(5) The presence of the narcotic, 0.5 mM sodium amytal, produces, with the unstimulated brain cortex slice, a marked increase in the yield from glucose uniformly labelled with carbon-14, of labelled γ -aminobutyric acid and alanine, with relatively small changes in the yields of labelled glutamate, aspartate and glutamine. With the stimulated brain cortex slice (that is, with 105 mM potassium ions) the narcotic at small concentrations brings about a very large fall in the yield of labelled glutamine, falls in the yields of labelled alanine and aspartic acid and a rise in the yield of labelled glutamic acid. These results may be adequately explained on the basis of the conclusions given above, together with the conclusion that the main effect of the narcotic is to suppress the oxidation of reduced diphosphopyridine nucleotide by cytochrome oxidase and its associated phosphorylations.

LETTERS TO THE EDITORS

OCEANOGRAPHY

Application of Ultra-Violet Lights to Underwater Research

We believe this to be the first report of the use of ultra violet lights by divers in underwater research. In addition to opening up a new technique of exploration, it is believed that our preliminary findings may be of considerable interest to marine biologists, geologists and archaeologists.

This work was conducted at depths of 3-5 fathoms in the waters of Northwest Harbor, Deer Isle, Maine, during August 1958, using hand carried ultra violet lights of our own development. Self-contained breathing apparatus ('Sonba') was used throughout and all dives were conducted at night.

Two ultra violet lights were used. Each light was completely self contained and consisted essentially of a G.E. tubular ultra violet lamp 6 watts (T-5, BLB self filtering) as an ultra violet light source (about 3500-4000 Å) which was energized by a 6 V battery-driven circuit consisting of an interrupter making and breaking the current to the low voltage side of a transformer (Stancor, A-3879). Sufficiently high voltage was obtained from the transformer secondary to cause a discharge through the ultra violet light tube. Acknowledgment is made to Transspace Laboratory for the use of their laboratory and workshop in the development of these lights.

Five preliminary findings merit presentation. (1) The general prevalence of fluorescence (often extremely beautiful) under ultra violet irradiation of much of the material matter and objects occurring growing and making up the ocean bottom, in the waters explored. (2) The difference in the observed fluorescence of many objects removed from the water and the same objects *in situ*—for example 'coralline algae' which out of water generally fluoresce rose or pink in their natural habitat appear to fluoresce white. (3) The apparent absence of any significant fluorescence of the suspended matter in the naturally turbid Maine waters, and the absence of any dazzling Tyndall beam phenomenon. This made it possible to see objects (which fluoresced) approximately eight times beyond the range at which such objects could be seen through these waters using natural light or during the daylight hours. Normal visibility is about 6 ft in these waters. At night using ultra violet light, fluorescent objects approximately 50 ft away could be detected. This latter suggests because of the natural fluorescence of the human skin (of light skinned persons) and the fluorescence of white clothing particularly clothing washed in modern detergents which contain optical whiteners, that searches in turbid and sediment-filled waters for bodies of the drowned might best be conducted in the dark, at night using ultra violet light. (4) The fluorescence of the bottom, in mud areas under which long submerged pieces of ships' timbers were known to be buried, appeared to be significantly different from areas which were free of timber. This suggests the use of ultra violet light as an aid in locating the

presence of artefacts buried in mud. (5) The fluorescence of naturally fluorescent petroleum intermixed with seabottom mud which suggests the possible value of ultra violet light in submarine prospecting for petroleum and fluorescent minerals.

The North Kenya Banks

A BANK off the northern Kenyan coast is acquiring significance. Its presence is unique along the coastline of tropical East Africa and it is of considerable interest as an abstract marine problem of this region and as a likely boost to local fishery resources.

Africa has least shelf area, relative to its size of all the continents and off tropical East Africa the shelf is particularly narrow. The 100 fathom contour off Tanganyika and Kenya usually lies only 2-5 miles offshore the only notable exception being the bank mentioned that is sketchily indicated in Admiralty Charts off Lamu, North Kenya. It is tiny compared to world fishery banks following about 40 miles of coastline and extending offshore to a maximum of about 30 miles. The chart suggests a simple bank but we have found there to be several banks with a very distinctive, steep valley separating the south western half of the bank complex from the shore at the normal position of the edge of the continental shelf. The offshore area has complicated topography 'irregular in configuration with hills and pits often side by side'. For example a lull rising to 58 fathoms lies less than 1 nautical mile from a pit dropping to 92 fathoms. At the blind end of the valley mentioned where the bank system runs into the shallows of Lamu Bay there is a sizeable area of apparently very smooth bottom at 42 fathoms and other regions of smooth bottom are to be found at greater depths although interspersed with undulant or rough areas.

Certain conjectures regarding the history of these banks are worth mention until geological examination (for which we are not equipped) reveals their structure. They are likely to consist of deltaic alluvium for the Lamu area is plainly the ancient delta of a river that was many times greater than the nearby present-day Tano River. The Tano now opens into the sea southerly of Lamu and its water is carried northwards by the coastal current throughout the year but meets, off Lamu, a southward flowing current for part of the year. It is reasonable to infer that precipitation of river sediment occurs off Lamu and this would perpetuate the ancient banks. In addition the folds and planities of the bottom as revealed by our explorations, strongly suggest to me an underpinning

by rock (although this is remarkable in view of the flat adjacent countryside) It is interesting that soundings from old and modern sources suggest shifts of alluvium from one place to another, yet no dispersion of the bank as a whole despite the currents that sweep it

Accounting for the presence of the banks is, perhaps, of abstract importance to their potential fishery value and so is explanation of the actual and unique association of fishes to be found. A rock-cod (*Serranidae*) can be caught in fair numbers but it has never been found by us south of the North Kenya banks. It is almost certainly the same species as one trawled off the south of India. Yet, below the water that comprises the surface coastal current other fishes can be plentifully caught that are common off south-eastern South Africa. Newell's² exposition of the current system of these waters is of great interest regarding the geographical distribution of the species.

By world standards the fishery production off British East Africa is infinitesimal³ due to primitive fishing methods, to the infertile sea water and to scarcity of shelf area. It is a pity that Worthington⁴ omitted emphasis of this last and vital factor in his memorable review of modern African biological resources, for it is a severe handicap to development. Demand for fish is great as shown by the annual importation of fresh fish from Europe and South Africa and of salt fish from Arabia and Somalia. Any increase in productivity would be tremendously important, and fortunately the North Kenya banks have been proved very promising^{5,6}. A few trawling trials have been made off this coast but most came to grief due to insufficient knowledge of suitable areas of clean bottom. Our departmental explorations in *M.V. Manihine* have now charted areas of the North Kenya banks where trawls may be cast with favourable chances and where, moreover, fishes have been caught on handlines. Even a small trawling ground would raise the annual harvest appreciably, for traditional fishing by handlining and trapping is time-consuming. Whether or not trawling proves feasible the rough areas on these banks yield commercially valuable fishes to handlining and may support longlining on the mother-ship and dory system, a development that the hardy local fishermen appear to be suited to.

The assay of commercial possibilities of handlining and trapping in certain rich areas is being done by the Provincial Fisheries Officer (Coast) of the Kenya Fisheries Division. Our Organization is tackling the wider exploration of the banks, principally charting, hydrography and fishing by various methods (but chiefly by handlines and reels loaded with wire) here, there and everywhere to see whether other rich areas are present and to obtain a fuller picture of the fishing potential. (A report is being prepared.) Clearly there are fishing grounds and I am attempting to determine the grounds in relation to benthos by dredging, but there is unfortunately little time available for this and for the lengthy process of identifying specimens and evaluating the benthic ecology. Extensive echometer work is being done to map smooth and rough areas. A bathythermograph is often cast into the deeper places for there is a segregation of fishes into those that frequent the surface current and those in the different body of water beneath. Knowledge of the depth of the thermocline between the two water layers helps to determine what species to fish for, and where to position the boat.

My hope is that other workers would like data or specimens for I would happily co-operate so that our

work on the North Kenya banks may achieve a scope beyond our present resources of time and man-power. With only one of our staff available for this investigation we restrict ourselves to aspects of direct fishery value.

PHYSICAL SCIENCES

An Absolute Scale of Time

PHYSICAL time is customarily measured by counting the number of times a suitably chosen cyclic process (for example an oscillating pendulum) is repeated, and equal intervals are defined as those during which the process is repeated the same number of times. It would, in principle, be possible to choose, instead of a cyclic process, a purely random one and define equal intervals of time as those during which random events are equally likely. Most random processes vary too much with environment (for example, molecular bombardment of a surface varies with temperature) to be selected as standards for measuring time but radioactive decay is believed to be virtually independent of environment. Thus, if radioactive decay is truly random, the number ΔN of nuclei disintegrating in a time-interval $t, t + \Delta t$, out of N like nuclei existing at time t is given by

$$\Delta N = -\lambda N \Delta t \quad (1)$$

where λ is a constant characteristic of the particular nuclei chosen.

Let a clock be constructed to count one every time an arbitrary fixed number of nuclei disintegrate from an assembly of N_0 like nuclei at $t = 0$, which has become N at time t so that

$$N = N_0 e^{-\lambda t} \quad (2)$$

The number disintegrating in the interval $t = 0, t = 1$ is $N_0(1 - e^{-\lambda})$. Let this be chosen as the arbitrary fixed number.

The number that have disintegrated by time t is $N_0(1 - e^{-\lambda t})$ so the time-interval X indicated by the clock (that is its count) will be $N_0(1 - e^{-\lambda t})/N_0(1 - e^{-\lambda})$ and

$$1 - e^{-\lambda t} = X(1 - e^{-\lambda}) \quad (3)$$

As judged by customary time-scales equal intervals by such a clock would appear to be getting longer and longer and the clock would be deemed unsuitable. Let there be a second clock of the same kind but using different nuclei the decay constant of which is μ , then for it we have

$$1 - e^{-\mu t} = Y(1 - e^{-\mu}) \quad (4)$$

where Y is the time indicated by the second clock which is just as unsuitable as the first one.

An additional observable quantity is dY/dX , the rate of one clock as judged by the other and we have

$$\frac{\mu e^{-\mu}}{1 - e^{-\mu}} = \frac{dY}{dX} \frac{\lambda e^{-\lambda}}{1 - e^{-\lambda}} \quad (5)$$

In equations (3), (4), and (5) X , Y and dY/dX are known so that λ , μ and t are calculable and t does not depend at all on the nuclei chosen, so from the two clocks a true or 'absolute' scale of time is derived and also the decay constants of the two sorts of nuclei chosen.

It is not suggested that a useful practical system of this sort could be constructed, the accuracy in practice obtainable in counting disintegrations is far too low by any presently known methods. Even if counting were perfect the fluctuations occurring in these random processes would make the attainment of anything like the precision of a good ordinary clock only attainable if the number of disintegrations counted per second of ordinary time was very large indeed, and there would among other difficulties be either that of ensuring that each clock was pure in the sense of the disintegrations counted all being of like atoms or of a much more complex analysis.

The interesting point remains that from two such clocks a scale of time could, in principle, be derived that is independent of their nature and could be of any desired precision if only the clocks contain enough atoms. The accuracy with which the derived scale matched conventional time might be a test of the truth of the assumption that the decay processes are random.

Perhaps, without stretching the significance of this curious result too far one may suggest it implies that providing the universe is not composed solely of identical particles but contains at least two sorts capable of random disintegration at different rates there is a natural rate of change inherent in the structure of the universe itself independently of any man-made timepieces.

Another point of interest is that, with any set of finite clocks of this kind, the uncertainty in measurement of a time interval increases without limit as the interval tends to infinity.

Signals from Satellite 1958 52 (Sputnik III)

In a recent communication Munro¹ reported Australian observations of the radio signals from Satellite 1958 52 which led to the conclusion that the pulse modulation was absent when the Satellite was not illuminated by the Sun. This lapse of modulation was first noted early in March.

There has been little opportunity for observers in Great Britain to detect such a lapse because on all near transits since late February the Satellite height has been sufficient for it to be illuminated over practically the whole of its observable track. There was, however, a short period from April 14 to 28 when the early part of the track was in darkness and observations made at the Radio Research Station Slough, during this period showed that the signals were not received as early as expected and did, in fact, not

commence until the predicted time at which the Satellite emerged from eclipse.

Up to the end of February and afterwards, except during the above period in April, signals have been received over the whole of the observable track. The condition of complete illumination on all near tracks continued until mid August.

The Radio Research Substation at Singapore has also reported the absence of signals at night. This lapse was first noted on March 27, and during June when the conditions were appropriate it was observed that the signals ceased abruptly within a minute of the predicted time of the Satellite passing into eclipse.

Although our results confirm Munro's observation of the lapse of modulation the c.w. signal during these lapse periods, which he also observed has not been detected so far either at Slough or Singapore. This may be due to lack of sensitivity in the receiver at Singapore and to the absence of suitable observing conditions at Slough.

This work was carried out as part of the programme of the Radio Research Board, and this communication is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

Upper Atmosphere Density Variations Due to Hydromagnetic Heating

This communication describes a mechanism which explains: (1) the irregular orbital accelerations of satellites^{1,2}, and (2) the sudden disappearance of trapped radiation from the *Argus* nuclear explosion coincident with a geomagnetic storm³. These two observations may be explained by the calculated rates of ionospheric heating by hydromagnetic waves⁴. The hydromagnetic waves are generated at a distance of six to ten Earth radii from the centre of the Earth by the instabilities as the solar wind interacts with the geomagnetic field, and by variations in solar wind pressure^{5,6}.

The major features of the satellite orbital decay to be explained are the correlation between the orbital acceleration and the 10 and 20-cm solar radio noise intensity and the increased orbital acceleration during magnetic storms. Since the orbital decay increases during a magnetic storm and not at the time of a solar flare Jacquin⁷ has concluded that it is probably corpuscular radiation from the Sun, that is the solar wind which affects the atmospheric drag. The corpuscular radiation itself cannot penetrate the geomagnetic field closer than about 5 Earth radii from the Earth's centre (except during severe magnetic storms). However, as stated above, the solar wind can generate hydromagnetic waves which will be dissipated as heat in the altitude range 150–200 km (the F₁ region of the ionosphere). The amplitude and frequency of the fluttering at the edge of the geomagnetic field varies with the strength of the solar wind⁸. Therefore the high temperature of the F₁ region, which is at least in part due to hydromagnetic heating⁴ will vary with the strength of the solar

wind Since the density above the *F*-region depends on the temperature of the *F*-region, the hydromagnetic heating provides the mechanism whereby the solar wind can affect satellite drag

The correlation between the 10- and 20-cm solar radio noise intensity and the orbital acceleration is independent of whether perigee is over the dark or sunlit hemisphere Since the hydromagnetic wave velocity varies with height in such a way as to refract the waves completely around the Earth⁸, the hydromagnetic heating gives a natural explanation of why the correlation between the 10- and 20-cm solar radio noise intensity (which is apparently an index of solar wind intensity) and the orbital acceleration is not affected when perigee moves from sunlight into darkness

The ionosphere will also be heated by the hydromagnetic waves which are generated during magnetic storms The magnetic storm fluctuations have periods of the order of minutes which are much longer than the steady state flutter periods of about 1 sec The hydromagnetic heating rate is dependent on frequency in such a way as to make the low frequency disturbance fluctuations much less effective for ionospheric heating than the 1 cps steady-state flutter frequency unless the amplitude of the low frequency fluctuations rises above some critical value Since the magnetic *K* index is a measure of the amplitude of the low frequency fluctuations and is not sensitive to the 1 cps flutter frequency amplitude, no correlation between orbital acceleration and *K* index should be expected unless the *K* index should rise to a rather high value (as it would during a magnetic storm) Thus, ionospheric heating by the large amplitude low frequency hydromagnetic waves generated during a magnetic storm can account for the increased orbital acceleration observed during magnetic storms⁷

The same general arguments may be applied to the sudden disappearance of electrons from the *Argus* nuclear explosion These electrons had been trapped in the geomagnetic field It has been shown⁴ that atmospheric heating will not distend the geomagnetic field even though the upper atmosphere expands (briefly, because (1) the slight increase in ion pressure is much less than the magnetic field pressure stress, and (2) even if the magnetic field were pushed out, it would very quickly diffuse back to its equilibrium position) Therefore, the shell of *Argus* radiation is fixed with respect to the earth and any ionospheric heating will increase the atmospheric density at the altitude of the *Argus* radiation This increase in atmospheric density will, of course, increase the rate of loss of the trapped particles The radiation intensity of the trapped *Argus* electrons was observed³ to decay inversely with time until a magnetic storm occurred Then, the rate of decay of radiation intensity increased markedly and the radiation disappeared in a few hours It has been pointed out that magnetic scattering of the electrons due to breakdown of the conservation of the magnetic moment is unlikely since the cyclotron frequency for electrons is too high and the cyclotron radius is too small for hydromagnetic waves to have any effect on the invariants of motion⁹ That is, the electron cyclotron frequency is much greater than the hydromagnetic wave frequency and the electron cyclotron radius is much less than the hydromagnetic wavelength so that the adiabatic conditions are maintained However, an increase in atmospheric density at high altitudes due to ionospheric heating would shorten

the trapping lifetime of the *Argus* electrons due to scattering by atmospheric gas Thus, the loss of the *Argus* radiation and the increased orbital acceleration during a magnetic storm may be taken to be two independent observations of the same phenomenon ionospheric heating by hydromagnetic waves

Another phenomenon which may be explained by hydromagnetic heating is the increased X-radiation intensity observed at balloon altitudes during a magnetic storm¹⁰ (These observations were made at latitudes far below the auroral zone and were not associated with visible auroras) The ionospheric heating increases the atmospheric density in the lower part of the Van Allen radiation belt and thereby increases the scattering loss of trapped particles The electrons which are scattered out of the Van Allen belt will emit bremsstrahlung upon being stopped in the atmosphere, and thus account for the increased radiation intensity measured at balloon altitudes during the magnetic storm This explanation requires that the intensity of the lower part of the Van Allen radiation belt decrease during a magnetic storm

The conclusion reached is that ionospheric heating by hydromagnetic waves (generated by interactions between the solar wind and the geomagnetic field) can explain (1) the observed variations in the orbital acceleration of satellites, (2) the sudden loss of the trapped *Argus* radiation coincident with a magnetic storm, and (3) the X-ray flux observed at balloon altitudes far below the auroral zone during magnetic storms This flux is presumably associated with changes in particle radiation intensity at the lower edge of the Van Allen radiation belt The hydromagnetic heating of the ionosphere produces the above effects by increasing the scale height of the atmosphere and thereby increasing the atmospheric density at high altitudes

Auroral Frequency Lines

In his recent letter, Dr B. Hultqvist¹ compares lines of equal auroral frequency drawn by E. H. Vestine and by C. W. Gartlein with auroral frequency lines deduced theoretically. He finds that his lines agree better with Gartlein's International Geophysical Year data in that both sets bulge much farther south of the geomagnetic latitude circles over north-east America than do Vestine's lines which were based on a combination of the original Fritz data with those collected in the years 1872-1942

This is interesting, but it is not surprising that the Vestine and Gartlein frequency-lines diverge and it can scarcely be taken as confirmation of the theory

behind Hultqvist's lines. As nearly as can be judged from his Fig. 1, he compares the position of Gartlein's once a year ($1/yr$) frequency with Vestine's $5/yr$ line which lies southward of it, and Gartlein's $70/yr$ line with Vestine's for $50/yr$ lying for the most part well north of it. Thus by itself would not be critical because the frequency lines of any one family should have the same general shape. But as the belt of greatest auroral frequency and associated geomagnetic disturbance expands southwards at times of greatest activity it is important that similar methods should be used for reducing different sets of data to a common basis of activity. It is also necessary that similar adjustments are made for incidence of cloud and daylight. In his redrawing of the Fritz lines, Vestine introduced corrections to his later observations based on the data from the British First and Second Polar Year Station at Fort Rae in the zone of maximum frequency in north west Canada. He also corrected for length of daylight. But there is no evidence that any similar procedure was used for Gartlein's International Geophysical Year data.

J. M. STAGG

Meteorological Office
Air Ministry
Kingsway
London, W C 2
June 18

Hultqvist *B. Nature* 183 1478 (1949)

DIFFICULTIES are certainly associated with the preparation of observational auroral frequency lines. In general some of the most important ones are supposed to be those due to too low density of the observational net, individual variations among the observers with regard to observational scheme and definitions, variations of the sensitivity of observational method, etc. Correction for variation of the solar activity over the observational periods for the different observers must be introduced. In addition to these adjustments for cloud and daylight must be made as mentioned by Dr Stagg.

The difficulties seem, however, to be least if only the frequency lines over a limited part of the Earth are to be determined, if the observational material is restricted to a fairly small period in time and especially if the net of observations is dense and all the observers are using the same nomenclature definitions and observational scheme.

This latter advantageous case is that of Gartlein who has had at his disposal the closest and best prepared net of well co-ordinated observers, which so far as I am aware has ever worked over American territory. In contrast Vestine has used a less homogeneous and less defined observational material obtained at fewer points in the United States as basis for his curves.

As Dr Stagg himself mentioned, the family of frequency curves may safely be supposed to have the same general shape over a wide range of absolute frequency values.

For the reasons mentioned it seems reasonable to suppose that the shape of Gartlein's curves are at least as reliable as that of Vestine's over American territory and to draw the conclusion of my earlier communication.

Polarization and Resolving Time Effects in Photon Correlation

SEVERAL papers¹⁻³ have been published recently reporting an enhancement of the coincidence rate due to photons detected by photomultiplier tubes viewing coherent light beams. Here we wish to report on the effect of varying several of the factors which influence the magnitude of the enhancement, in particular the degree of polarization of the beam and the resolving time of the coincidence apparatus. The variation of the enhancement with spectral line width (0.006 \AA and 0.009 \AA) has been reported previously² to be in agreement with the theoretical predictions.

To obtain simultaneous recording of two resolving times ($2\tau = 8 \times 10^{-9} \text{ sec}$ and $4 \times 10^{-9} \text{ sec}$) as well as to simplify the running of the experiment the cable switching was made automatic and new coincidence circuits were designed similar to those described by Moody⁴. This change from our previous experimental arrangement, which used a Bell-Graham and Petch coincidence circuit⁵ with manual switching in addition gave improved accuracy. Long ($20 \times 10^{-9} \text{ sec}$) and zero relative delay cables were automatically switched over 30 seconds. The light source was an electrodeless mercury 198 discharge tube in a coaxial chamber⁶ excited by 2450 Mc/sec radio frequency power. This lamp was water-cooled, the water temperature being regulated at 45°C and run near the maximum intensity. The 5461 \AA line of mercury was isolated by means of Schott filters. Several types of experiment were performed, alternating the mercury 198 lamp with a high pressure mercury lamp alternating the cases of photomultipliers 'superimposed and displaced sufficiently for the coherence to drop to zero and alternating the cases with a polarizing filter in the beam and without this filter.

The results of the experiments may be expressed in terms of the enhancement of the counting rate for zero delay over that for long delay after the attenuation corrections have been applied. These corrections were obtained by measuring the counting rates with one photomultiplier displaced so that the coherence factor was zero. As a check on the performance of the equipment a high pressure mercury arc producing a broad emission line (about 1.5 \AA wide) was used as the light source several times during the course of the experiment. With the mercury 198 lamp (unpolarized light) the observed enhancement was 0.0087 ± 0.0008 for $8 \times 10^{-9} \text{ sec}$ resolving time. For plane polarized light the predicted enhancement^{1,2} is twice the value for unpolarized light. To compare with this prediction a Polaroid filter was placed between the lamp and the pinhole. Under these conditions (polarized light) an enhancement of 0.0230 ± 0.0042 was obtained 2.75 ± 0.73 as large as that without the Polaroid. For a resolving time of $4 \times 10^{-9} \text{ sec}$ with polarized light an enhancement of 0.0300 ± 0.0047 was obtained, 3.45 ± 0.86 as large as the value for unpolarized light with a resolving time of $8 \times 10^{-9} \text{ sec}$ compared with an expected factor of four.

The experimental variation of enhancement with resolving time, polarization of the beam and spectral line width have been found to be in agreement with theory¹⁻³ within the experimental error. Further experiments are being carried out in order to obtain increased accuracy and to obtain results under different conditions.

We are indebted to the National Research Council of Canada for the financial support of this research programme

Experiments on the Acousto-Electric Effect

PARMENTER¹, and later Gurevich², predicted that a single longitudinal acoustic wave passing along a metal or semiconductor should produce a steady potential difference in the material. Weinreich and White³ and Sasaki and Yoshida⁴ observed the effect in germanium.

We have attempted to observe the acousto electric effect in copper and aluminium. In our most conclusive experiment, vibrations of high energy, at 25 kc/s, produced by an ultrasonic drill were passed along a copper wire, and were absorbed at the other end by a mass of 'Plasticine' to prevent reflection. The particle amplitude of the specimen was observed under the microscope. The vibrations were continuous over the whole length of the wire from the transducer to the absorber, showing that no standing waves were formed.

The acoustic energy in the wire was calculated to be about 9 watts, and its diameter was 0.07 cm, giving an intensity of 2000 watts/cm². According to Parmenter's theory this should produce an acousto-electric e.m.f. of 400 μ V/cm. (For a good conductor, Gurevich calculated an even higher e.m.f. of 0.3 μ V/cm for each 0.1 watt/cm² acoustic intensity.) In actual fact, we observed at most only 1.4 μ V on a specimen of 25 cm length, and also on another of 150 cm length. (The smallest detectable signal was about 0.3 μ V.) As this potential difference required an appreciable time to appear and to disappear, it was probably due to heating effects. Thus the observed effect would be at most only a very small fraction (about 1/7000) of that predicted by the theory.

In an earlier experiment high-energy pulse trains, of 300 kc/s, were produced in a nickel magnetostriction tube and passed along an aluminium specimen. No effect was observed.

The tests were carried out at room temperature.

Intensity of the (111) Reflexion for Diamond

RECENTLY¹ the intensity of the (111) reflection of diamond was measured. A value was found which deviated from that given formerly² but which agreed with the value based on McWeeny's³ calculations of the atomic scattering factor for carbon.

F-values given in the recent publication¹ were calculated from the experimental data using the absorption coefficient for CuK α -radiation $\mu/\rho = 4.52$ as given in Compton and Allison, p. 802, Table 1 (1942) and also in D'Ans-Lax, "Taschenbuch für Chemiker und Physiker", p. 83 (1949). But, since also the higher value of 5.50 is cited (for example, "Internationale Tabellen zur Bestimmung von Kristallstrukturen", 1935), and because the absorption coefficient also was found to vary from crystal to crystal,² a determination of μ/ρ was carried out on the sample used for the above-mentioned measurements. It was found that $\mu/\rho = 5.56 \pm 0.14$.

With this absorption coefficient the mean value of f_{111} determined by the reflection-method becomes 2.39, and the weighted mean of all experimental values, that is, including the data obtained by the transmission method (which are independent of μ), is 2.35 in agreement with the former determination². It must be concluded, therefore, that while for higher $\sin \theta/\lambda$ values the agreement of measurements and McWeeny's calculations is generally good, an appreciable discrepancy is present at $\sin \theta/\lambda = 0.141$, that is, for f_{111} at diamond.*

It can be shown that this is due to the fact that the accumulation of binding electrons between two carbon atoms in diamond which gives rise to the appearance of 222, also strengthens the intensity of 111. It does not influence 220, however, and the experimental value of f_{220} agrees, indeed, accurately with McWeeny's calculation. On the other hand, f_{311} is expected to be weaker and this is also in agreement with the experimental observation². At higher orders these effects fade out. The details and an extended discussion will be given elsewhere.

Fibre Surface Replication by Rolling

A TECHNIQUE for replicating fibres by rolling has been developed in these laboratories. It is only applicable to fibres which approximate to a cylindrical shape, such as nylon, 'Terylene' and wool, but with these it can give replicas with sufficient resolution for the full magnification available in light microscopy. It is not known yet to what extent the replicas are suitable, either directly or in second stage form for electron microscopy.

A glass microscope slide is dipped in 'Necol' cement (diluted with acetone to more than three times its volume) and allowed to dry, protected from dust. When it is sufficiently dry to be non-tacky, three lengths of fibre, each about 3 mm long, are placed on

the 'Necol' film in a triangular array, the fibres parallel to the short side of the slide. Another glass slide is laid on top, then, while slowly pulling the top slide along so as to roll the fibres, a weight between 200 and 500 gm is carefully applied above the fibres to press them on to the 'Necol' film.

'Necol' cement which is principally based on nitro cellulose has been used so far as the replica medium. Other possible media are also being tried. We produce the steady motion of the top slide (10 microns/sec) by coupling it to a considerably geared down 'Drayton' motor.

The photographs illustrate the use of the technique on nylon and wool. Fig 1 shows a replica of a scratched length of an undrawn nylon filament clearly demonstrating the repeated replication of the fibre surface. This technique provides a means of checking on one replica by the occurrence of identical detail at intervals across the replica that the features reproduced are produced by the replication and are therefore presumably true fibre surface detail.

The distribution of surface detail over the whole fibre circumference is also immediately available on one replica and a better understanding of the significance of any particular feature is obtained.

Fig 2 is at a higher magnification, showing one

Fig 2 ($\times 200$)Fig 1 ($\times 50$)

complete revolution of a wool fibre. Both photographs are taken in phase contrast. Fig 1 with a numerical aperture of 0.28 and Fig 2, 0.65.

I am indebted to Miss J. I. Tidmarsh for the photographs, Mr J. F. Williams for valuable collaboration in developing the technique and to British Nylon Spinners Limited for permission to publish this communication.

CHEMISTRY

Rotational Friction Coefficients of Models of Tobacco Mosaic Virus and the Size of the Virus Particle

Much valuable information about the shape of macromolecules in solution can be derived from hydrodynamic studies. Two recent measurements of the rotational friction coefficient of tobacco mosaic virus, by the electro-optical effect¹ and by flow

birefringence², have, however, led to values of the length that were more than 10 per cent greater than the length observed in the electron microscope³. This serious discrepancy which is well outside the presumed experimental errors, could be explained by changes in the dimensions of the virus particle on drying, or by failure of the available hydrodynamic formulae adequately to describe the actual behaviour of the rod shaped particle.

It has been generally believed that the hydrodynamic behaviour of this highly asymmetric cylindrical particle (axial ratio 20:1) is practically the same as that of a prolate ellipsoid of the same length and axial ratio, for which an exact formula is available. This belief has been strengthened by an approximate calculation of Burgers⁴, which gave a result for the cylinder that was almost the same as the ellipsoid. The rotational friction coefficient, C , is the torque needed to make an object rotate about a given axis at unit angular velocity in a viscous fluid that has stationary boundaries at infinity. For a prolate ellipsoid of semi axes a and b , Perrin obtained⁵ (for a/b large)

$$C = 8\pi\eta a^3/3 [-0.50 + \ln(2a/b)] \quad (1)$$

For a cylindrical rod Burgers⁴ obtained the same formula except that the negative constant in the denominator was 0.80 instead of 0.50. For an object with a/b equal to 20 the values of C calculated from the two formulae differ by only 11 per cent.

Since the Burgers's formula is admittedly approximate, it was decided to test the validity of the hydrodynamic equations directly by studying models of tobacco mosaic virus were carefully inclined from brass. An ellipsoid and a rod were made having an axial ratio of 20:1 and a length of 10.16 cm. Another rod of similar dimensions was made having hemispherical ends. Another cylinder had the same axial ratio but was half as long (5.08 cm). Experiments were also made with a polymethyl methacrylate sphere having a diameter of 5.38 cm.

Experimental determinations of torque were made by suspending the models in the centre of an oil bath from fine calibrated tungsten torsion wires. Silicone oil was used for most of the experiments but confirming experiments were also made in a mineral oil of comparable viscosity. The cylindrical oil bath was mounted on a turntable and rotated about its axis at speeds from 0.3 to 1.3 r.p.m. Torque was invariably found to be proportional to speed. Reynolds's numbers were estimated to be far below the turbulent range.

For the experimental values of C to be meaningful the walls of the vessel must not interfere. A rough estimate of the effect of the walls on the torque N can be obtained from an equation given by Lamb⁶ for a spherical container

$$N = N_\infty (1 + N_\infty/6\eta\omega I) \quad (2)$$

where N_∞ is the torque in a vessel of infinite radius, V is the volume of the container, and ω is the angular velocity. One can argue from dimensional considerations that a very similar equation should also be valid for cylindrical containers. For the vessel used the error is estimated in this way as less than 1 per cent compared to a reliability in the measurement of ± 2 per cent.

The experimental frictional coefficients are summarized in Table 1. The value for the sphere agrees with theory quite closely, which confirms the validity of the experimental procedure. The value for the ellipsoid is too large by an amount outside experi-

mental error. This is believed to be due to errors in the machining of the shape, since the volume of this model was measured and found to be about 4 per cent greater than expected. The rod with hemispherical ends has a frictional coefficient somewhat lower than the rod with square ends, demonstrating the importance of the geometry at or near the end of the rod. The data for the smaller rod are much less precise due to the reduction of sensitivity in the measurement, but they can be taken as a satisfactory confirmation of the a^3 relationship. The most noteworthy point, however, is the difference between the rod and the ellipsoid. The data given show very definitely that the rotational friction coefficients for rods having the axial ratio of tobacco mosaic virus are much higher than earlier calculations indicated. Apparently tobacco mosaic virus cannot be adequately represented by an ellipsoidal model, since the friction coefficient of the rod is 56 per cent greater than that of the equivalent ellipsoid. Burgers's approximation is also inadequate for the virus since it predicts only an 11 per cent difference.

Table 1 FRICTIONAL COEFFICIENTS (DYN/CM/SEC/RAD) IN SILICONE OIL AT 25°C $\eta = 54.4$ CP

| Shape | Experimental C | Calculated C | Ratio |
|--------------------------------|------------------|----------------|-------|
| Sphere | 284 | 266 1* | 0.932 |

* Formula of Stokes

† Formula of Perrin (ref. 5)

‡ Formula of Burgers (ref. 4)

S. Broersma (private communication) has recently made improved calculations for the rotational diffusion constants for cylindrical particles. His results indicate a value for C within 10 per cent of our experimental value.

A revised length for the tobacco mosaic virus particle can now be calculated, assuming that C varies as ηa^3 at constant axial ratio. The relevant data are the value of 292 for C for the rod of length 10.16 cm in an oil of viscosity 54.4 cp, and the value of 1.24×10^{-16} previously found¹ for C for tobacco mosaic virus in water at 0.894 cp. The length of the virus particle comes out to be 3000 ± 50 Å, in excellent agreement with the value of 2980 ± 10 Å found for the dry particle under the electron microscope.² The flow birefringence measurements of Boedtker and Simmons³ now also agree. In these calculations we have tacitly assumed an axial ratio of 20, corresponding to a diameter of 150 Å, which is, in fact, the diameter of the virus as determined by X-ray scattering.⁷

It can be concluded that the dimensions of the tobacco mosaic virus particle in solution are not significantly different from those in the dry state. This precludes the notion that tobacco mosaic virus carries with it a large, rigid, ice-like hydration shell as has been suggested for some proteins and nucleic acids.⁸

We are indebted to Prof. Broersma for showing us his work in advance of publication.

A Modified Rotating-Sector Method of Measuring Kinetic Chain Lifetimes

In order to evaluate the individual velocity coefficients for the propagation and termination reactions involved in polymerization and other chain processes, it is necessary to measure the lifetime of the kinetic chain. This is usually done by means of the rotating-sector method¹, or one of the non-stationary state methods²⁻⁶. The main disadvantage of the former method is that the complete determination of a kinetic chain lifetime cannot normally be made with a single filling of a dilatometer, unless the reaction is taken beyond the initial stage which may lead to gel effects and other complications. A number of dilatometers are therefore usually employed in a single determination of a lifetime, and errors often occur due to difficulty in reproducing the exact conditions, especially when the monomer involved is difficult to purify. The non-stationary state methods, on the other hand, yield a value for the lifetime in <30 sec, but unfortunately they often are inaccurate when lifetimes of <0.5 sec occur, since instrument lags or personal response times become particularly important for the very short lifetimes. The actual rate measurements, however, are quite accurate in this range of lifetimes, and can be measured in about 10 sec, that is, when 0.01 per cent reaction has occurred. By combining the two methods it is possible to cope with lifetimes of ± 0.5 sec, and to carry out a complete determination of a lifetime of the kinetic chain before 1 per cent reaction has occurred. The method is not valid for lifetimes ≥ 0.5 sec, since when flashtimes of several seconds are used the measurement of the rate by non-stationary state methods becomes inaccurate.

The procedure employed was to measure the reaction rates for a series of different sector speeds as in the normal rotating-sector method¹, but the rates were obtained from the expansion/time plots as in the dilatometric non-stationary state method⁶ instead of the usual contraction/time curves. By so doing, it was possible to obtain a rate determination in approximately 10 sec compared with about 20 min by the contraction method. This clearly reduces the

extent of conversion involved in a given number of rate measurements by a factor of more than 100

This combined method has been used in evaluating the ratio of the velocity coefficients of propagation to termination (k_p/k_t) at 25°C for the polymerizations of acrylonitrile in dimethyl formamide solution (30/70 v/v) initiated with 3.8×10^{-3} moles/l *azobisisobutyronitrile*, and of vinyl chloride initiated by 8×10^{-3} moles/l bromotrichloromethane. The values obtained were 3.4×10^{-4} and 7.1×10^{-7} respectively. Values of the ratio of the sectored to unsectored rate for a number of different flash times obtained in vinyl chloride polymerization are given together with the theoretical plot in Fig. 1. It will be seen that the experimental points lie mainly on the theoretical curve and that the agreement is better than is often obtained in the normal sector method

Fig. 1. Ratio of sectored to unsectored rates against log (flash time) for the polymerization of vinyl chloride at 25°C. \circ Experimental points — theoretical curve

Thermal Decarboxylation of Some Keto-Acid Hydrazones

The 2,4-dinitrophenylhydrazones of keto acids are frequently used to identify these metabolic intermediates. The clear statement by Clift and Cook¹ regarding the ready thermal decarboxylation of the 2,4-dinitrophenylhydrazones of oxaloacetic and acetoacetic acids has sometimes been overlooked, particu-

larly in the use of melting points as a means of identification. Some of our observations bear on the problem.

Oxaloacetic acid 2,4-dinitrophenylhydrazone (I) synthesized by the usual procedure, when inserted into a bath at about 190°C or above, melted with vigorous bubbling and resolidified immediately, with a final melting point of 214°C. The substance after resolidification (II) was re-analysed by paper chromatography (*n*-butanol/ethanol/0.5 M ammonium hydroxide 7:1:2 in the dark) and was recrystallized. After paper chromatography the spot was eluted and examined spectrophotometrically. Authentic samples of *trans* (III) and *cis* (IIIa) pyruvic acid-dinitrophenylhydrazones were prepared by the method of Katsuki et al.² As shown in Table I, (I) was decarboxylated to

Table I. PROPERTIES OF 2,4-DINITROPHENYLHYDRAZONES

| Substance | R_F | Melting point (deg. C. corr.) | λ_{max} (nm) |
|-----------|-----------|-------------------------------|----------------------|
| I | 0.05-0.11 | 214 (final) | 450 |
| II | 0.55* | 217 | 446 |
| III | 0.55 | 217† | 446 |
| IIIa | 0.56 | ? | 416, 530 |
| IV | 0.57 | 123 (final) | 437, 524 |
| V | 0.55 | 123 | 430, 524 |
| VI | 0.55 | 123‡ | 430, 524 |

* With large sample a weak spot of *cis* pyruvic acid-dinitrophenylhydrazone was also found.

† Mixed melting point of II and III 217°C. of V and VI 123°C.

‡ Melting point not sharp because of thermal isomerization to *trans* form.

pyruvic acid dinitrophenylhydrazone (chiefly *trans*) under these conditions. When (I) was heated slowly from a lower temperature, for example 100°C, double melting was not observed and only the melting point of 214°C was obtained. Under these conditions too chromatography showed that most of the hydrazone was converted to (II) during the longer heating.

When acetoacetic acid 2,4-dinitrophenylhydrazone (IV) was placed in the bath at about 115°C or above it melted, bubbled and resolidified, the final melting point was 123°C. The resolidified material after recrystallization (V) also melted at 123°C. Thus, (V) is acetone 2,4-dinitrophenylhydrazone as shown by comparison with an authentic sample (VI). This conversion also took place when the heating was done slowly from a lower temperature but only a single melting at 123°C was observed.

The melting point of the 2,4-dinitrophenylhydrazones is not a reliable criterion for confirmation or identification of oxaloacetic or acetoacetic acids. Resolidification during melting point determination was observed by Snell³ with a ketosuccinic acid—dinitrophenylhydrazone but no explanation was suggested.

This investigation was supported by Grant C-4342 from the National Cancer Institute, U.S. Public Health Service.

Synthesis of Boron Phosphide and Nitride

A NOVEL technique has been found for the synthesis of boron nitride and phosphide involving thermal decomposition of halide addition compounds. Further work is intended on the reactions involved but the information thus far obtained is felt to warrant a brief, preliminary report for the benefit of other workers in this field.

The addition compound BCl_2PCl_2 was prepared by refluxing phosphorus pentachloride in triethanolamine and passing boron trichloride into the reaction mass. The white product obtained was filtered off, washed with ether and dried *in vacuo* at room temperature. Samples were then sealed into Carius's tubes and heated under their own pressure development to about 300°C . Thermal dissociation occurred with the production of chlorine, some sublimation of the addition compound and deposition of a material on the tube walls. The colour of the deposit varied through the length of the tube and from experiment to experiment, from white through brown to black. On breaking the tube after cooling, chlorine gas escaped, residual addition compound was then decomposed and washed out with water and the film deposit also floated out on to water. The film was very resistant to hydrolysis and thermal decomposition, and could be heated in air to temperatures in excess of $1,000^\circ\text{C}$ without decomposition or apparent loss of integrity. X-ray and chemical analysis showed the material to be essentially cubic boron phosphide.

Further samples of the film were reheated at 800°C in a flowing atmosphere of 5 per cent ammonia in nitrogen when even the darkest film became white in colour and phosphine was evolved. X-ray analysis of the product showed it to be cubic boron nitride.

Addition compound was prepared from phosphine and boron tribromide or trichloride. When submitted to direct heating *in vacuo*, thermal dissociation immediately occurred, yielding again a film deposit of boron phosphide, but in better yield than before. Analysis of several specimens prepared under apparently similar conditions showed the product to vary between BP and B_2P_3 . A mixture of boron phosphide samples produced by the second reaction was submitted to reaction with dilute ammonia gas and again yielded boron nitride of cubic structure.

Thermal decomposition of BCl_2PCl_2 or BBr_2PCl_2 has not yet been examined, but it is felt that similar results would obtain in these systems.

The reactions involved would appear to be

Addition compounds of boron and phosphorus halides have been known for several years, but the process of their thermal decomposition does not appear to have been investigated before. It would seem possible that this mode of metalloid reaction might also be applicable to other similar systems.

Fuller experimental details shortly will be submitted for publication elsewhere.

3,4, ω -Trihydroxyacetophenone 3-methyl Ether in Adrenal Extracts

IN the course of the isolation of aldosterone from adrenal gland extracts ('Eucortone', Allen and Hanbury), the English authors detected a compound with properties similar to aldosterone in certain paper and column partition systems. This compound had ultra-violet absorption peaks at about 230 m μ and 280 m μ and gave a positive reaction with the $\text{FeCl}_3\text{-K}_3\text{Fe}(\text{CN})_6$ reagent. It therefore seemed probable that it was phenolic¹. It also gave a blue fluorescence on irradiation with ultra-violet (compound X)² and reduced blue tetrazolium at about the same rate as steroids having an α -ketol side chain. The compound ran as though slightly more polar than aldosterone in the Bush B_5 paper system³ and could be completely separated from the steroid by column chromatography using the same solvent system².

Preliminary work⁴ on a very small scale led to the conclusion that aldosterone did not absorb maximally at 240 m μ . It now seems likely that this was due to the presence of the phenol as a contaminant. The combined peaks of the phenol and aldosterone at 230, 240 and 280 m μ tend to give a flat absorption curve obscuring the single peak of the steroid. On separation of the phenol from aldosterone on the column, the steroid had maximum absorption² at about 240 m μ .

A fairly pure sample of the phenol, which was not crystalline, was sent to the Swiss authors who later, during large-scale isolation work on aldosterone using freshly frozen adrenal glands as source of material, isolated the compound in crystalline form and determined its structure as 3,4, ω -trihydroxyacetophenone 3-methyl ether. This has been confirmed by synthesis. The later work will be reported in detail elsewhere.⁵

Incorporation of DL-[2-¹⁴C] Mevalonic Acid Lactone into Polyisoprene

THE incorporation of DL-3-hydroxy-3-methyl-[2-¹⁴C] pentano-5-lactone (DL-[2-¹⁴C] mevalonic acid lactone) (MVA) into cholesterol in rat-liver homogenates was first demonstrated by Tavormina, Gibbs and Huff¹. Subsequent work showing that this lactone is incorporated into squalene² and β -carotene³ supported the view that mevalonic acid, or a derivative containing the same branched carbon atom structure, is directly involved in the biosynthesis of a wide range of polyisoprenoid compounds. Park and Bonner⁴ showed that when MVA is incubated

with freshly tapped *Hevea* latex it is incorporated into polyisoprene, although the reported efficiency of conversion was only about 2 per cent. Gascoigne and Jones¹ however were unable to observe the incorporation, *in vitro*, of MVA into rubber with the aid of fresh latex. We now wish to report an investigation which fully confirms the conclusions of Park and Bonner.

In our preliminary experiments, in which MVA was incubated with diluted fresh *Hevea* latex, no appreciable activity was detectable in the rubber. However, when undiluted fresh latex was used as described below, the MVA was converted into polyisoprene with an efficiency considerably higher than has been reported hitherto. It was also established that the polyisoprene formed was of high molecular weight.

Two aliquots of freshly tapped undiluted latex from 7 year-old seedlings of *Hevea brasiliensis* were incubated with MVA under the conditions shown in Table 1. Each reaction mixture was then coagulated with methanol and a weighed portion of the coagulum was placed in compartment X of the extraction apparatus (Fig. 1). This was constructed so as to

Fig. 1 Extractor

reduce manipulative losses in the subsequent treatment of the rubber. The coagulum was dispersed over the walls of the central portion of X by slow rotation of the vessel after the addition of oxygen-free chloroform, care being taken to prevent the rubber from coming into contact with the sintered glass disk. After removal of the chloroform *in vacuo* the dry rubber film was weighed *in situ* and extracted with acetone for 24 hr to remove unreacted MVA and other non-rubber components. The soluble fraction of the rubber was dissolved in chloroform-ethanol (97:3 w/w), intermittent operation of the magnetic stirrer causing the level of solvent in the outer tube to rise to Y and then fall. This ensured efficient extraction of the film, insoluble material being retained above the sintered glass disk.

To remove any compounds of low molecular weight, the rubber solution was dialyzed against three changes of the chloroform/ethanol solvent in alkali-pre-treated cellophane tubing which was

readily permeable to β -carotene but practically impermeable to polymers with molecular weights of about 100,000. Subsequent experiments also showed that mixtures of β -carotene and natural rubber could be separated quantitatively using the same membrane. The rubber was then ozonized in ethanol/chloroform (1:3 v/v) the ozonide being decomposed with a mixture of hydrogen peroxide and formic acid², and the product converted to the 2,4-dinitrophenylhydrazone. The latter was purified via the sodium salt. After two recrystallizations from aqueous acetic acid this material had a melting point of 199–200° C (uncorrected) and gave a single spot of the same R_f value as authentic levulinic acid dinitrophenylhydrazone (LADNP) when chromatographed on paper with *n*-butanol/ethanol/ammonia as the solvent⁴. Isotope dilution of the recrystallized levulinic acid dinitrophenylhydrazone, using an authentic sample of inactive material and recrystallization of the mixture from ethanol/pyridine also indicated a high degree of purity for the final active levulinic acid dinitrophenylhydrazone. All radiochemical assays of the various rubber fractions and the derived levulinic acid dinitrophenylhydrazone's (Table 1) were carried out using a standard gas-counting technique, with a counter having an efficiency of 45 per cent.

* Corrected for any inactive carbon atoms introduced.

The results of experiment 2 show that the soluble rubber (84 per cent w/w of the coagulum) was converted to levulinic acid dinitrophenylhydrazone in 75 per cent yield. The fact that a highly purified sample of the latter had at least 93 per cent of the specific activity of the dialyzed rubber shows that the active constituent had been degraded to levulinic acid in a similar yield. There is little doubt that only polyisoprene could give levulinic acid with such efficiency. The increase in [¹⁴C]-activity of the rubber after dialysis indicates the removal of some

active material of low molecular weight. Spectroscopic analysis shows that carotenoid material was removed by the acetone extraction, and none was present in the chloroform-soluble rubber (limit of detection less than 10 μ gm per gm of rubber). The increase in [14 C]-activity with time of incubation is further strong evidence that enzymic conversion of MVA occurred rather than physical adsorption of impurities on the rubber. Taking the corrected value of 14,600 c.p.m./mole of active carbon dioxide for the purified α -lactone acid dimethylphenylhydrazide from experiment 2, and assuming all the carbon in the dialysed rubber was polyisoprenoid, calculation shows that 9.3 per cent of the mevalonic acid lactone was transformed into chloroform soluble polyisoprene of high molecular weight.

We wish to thank Prof M. Stacey and Dr E. G. Cockbain for their interest and encouragement.

BIOCHEMISTRY

O-Phosphorylated and Unphosphorylated Peptide-Substrates suitable for Trypsin Action

A PREVIOUS communication reported the synthesis and action of trypsin on α -carbethoxy-L-lysyl-L-seryl-glycine and its O-phosphorylated analogue¹. The striking resistance of the latter to the action of trypsin throws additional light on the unusual resistance of various phosphopeptides obtained from casein. It was, however, felt to be of interest to further investigate the inhibitory role of the O-phosphoric acid residue of serine along different lines.

First it was felt necessary to exclude the possibility that a lysylserine sequence is not attacked by trypsin unless the hydroxyl group of serine is free. Therefore, α -carbethoxy-L-lysyl-L-(O-acetyl)seryl-glycine was synthesized as follows. α -Carbethoxy-L-lysyl-L-seryl-glycine benzyl ester¹ was treated with 100 per cent excess of acetic anhydride in dry pyridine to produce α -carbethoxy-L-(ϵ -carbobenzoxy)-L-lysyl-L-(O-acetyl)seryl-glycine benzyl ester (I), melting point

163–164° C, $[\alpha]_D^{20}$ –17.6° (c, 1.7 in acetic acid), almost in quantitative yield. Analysis calculated for $C_{25}H_{40}N_4O_{10}$, C 59.22, H 6.4, N 8.9, found, C 59.60, H 6.61, N 9.04. Hydrogenolysis of I afforded α -carbethoxy-L-lysyl-L-seryl-glycine (II) with an $[\alpha]_D^{20}$ value of –22.5° as a 1 per cent solution in water. Compound II was incubated with trypsin in 0.2 M tris(hydroxymethyl)aminomethane hydrochloride buffer pH 8.25 at 25° C. Ascending paper chromatography in butanol/acetic acid/water (4:1:5) revealed complete splitting of the lysylserine bond in the above tripeptide derivative after 30 min. When the course of the hydrolysis was followed by colorimetric ninhydrin analysis², surprisingly enough, a decrease in the colour yield was observed after 3 min (Fig. 1). This could be well explained on the assumption that the amino-group of the O-acetyl-L-seryl-glycine, resulted from the cleavage of II, was gradually masked by an O→N acetyl shift. To confirm this hypothesis, O-acetyl-L-seryl-glycine was synthesized by acetylation of carbobenzoxy-L-seryl-glycine benzyl ester³ in a manner similar to that described for the synthesis of I. Hydrogenolysis of carbobenzoxy-L-(O-acetyl)seryl-glycine benzyl ester, melting point 113–116° C, afforded O-acetyl-L-seryl-glycine (III) with an $[\alpha]_D^{20}$ value of +5° as a 1 per cent solution in water. Paper chromatography in butanol/acetic acid/water (4:1:5) revealed one ninhydrin-positive spot.

Samples of III were tested under the experimental conditions used for the enzymic digestion of II. A similar decrease in the colour yield, either in the presence or the absence of trypsin was also detected (Fig. 2). This again is in agreement with the assumed O→N migration of the acetyl group and strongly supports the following series of reactions:

Guttmann and Boissonnas⁴ have also mentioned an O→N acetyl shift in the case of O-acetyl-L-seryl-L-tyrosine over pH 7.

As the next step it was of interest to study the effect of an uncharged phosphoric acid derivative attached to the hydroxyl group of α -carbethoxy-L-lysyl-L-seryl-glycine.

Though there are several analogues that come to mind, the one having a diisopropylphosphoryl residue at this position held special interest to us. For its preparation α -carbethoxy-(ϵ -carbobenzoxy)-L-lysyl-L-seryl-glycine benzyl ester¹ was treated with 100 per cent excess of diisopropylfluorophosphate in dry pyridine to give α -carbethoxy-(ϵ -carbobenzoxy)-L-lysyl-L-(diisopropylphosphoryl)seryl-glycine benzyl ester, (IV), melting point 175–176° C. Analysis calculated for $C_{35}H_{51}N_4O_{13}$, N 6.91, found, N 6.80. Hydrogenolysis of IV produced α -carbethoxy-L-lysyl-L-(diisopropylphosphoryl)seryl-glycine (V) with an $[\alpha]_D^{20}$ value of –23° as a 1 per cent solution in water.

When V was subjected to the action of trypsin for 30 min and the incubation mixture was then checked by paper chromatography, the lysylserine bond was found to be almost completely hydrolysed. In this connexion it was ascertained that the substrate V suffered no loss of its diisopropylphosphoryl residue by β -elimination⁵ under the experimental conditions described here.

The course of the enzymic hydrolysis of V by trypsin was also followed by colorimetric ninhydrin analysis², the result of which is indicated by Fig 1

Fig. 1. Hydrolysis of various *o*-carboxy L-lysyl L-serine derivatives (0.01 M) with trypsin (0.017 mg/ml crystallized twice 50 per cent MgSO₄, Lot 3388 Mann) in 0.2 M Tris buffer pH 8.25 at 25°C. □ *o*-Carboxy L-lysyl (0-difluorophosphoryl)-L-serine; ○ *o*-carboxy L-lysyl L-serine; ● *o*-carboxy L-lysyl-(*o*-acetyl)-L-serine

Fig. 2. 0.01 M solution of *o*-acetyl L-serine in 0.2 M Tris buffer, pH 8.25 at 25°C. ○ Trypsin added (0.022 mg/ml crystallized twice 50 per cent MgSO₄, Lot 3388 Mann); ●, no trypsin added

Thus it appears that a substituted and uncharged phosphoric acid residue at the vicinity of the trypsin sensitive peptide bond does not even retard the hydrolysis of this particular bond by means of steric effect. However, a phosphoric acid residue at this position, probably due to its negative charge³ renders the susceptible peptide bond resistant to tryptic action

Work is in progress on the inhibitory spectrum of the *O* phosphoric acid residue of serine

Unidentified Growth Factors

It is well known that spent wash (the liquor remaining in the whisky still after distilling the spirit) contains factors which increase the growth of chicks. This growth promotion appears to be unrelated to mineral components, and although complementary to the effect of penicillin in chick feed², it may similarly result from changes in the gut flora³.

In an attempt to test this theory, chicks were fed with a control diet supplemented with procaine penicillin or with malt distillers dried solubles (made from spent wash). Comparison of the duodenal contents of chicks fed with either type of supplemented diet, or with the control diet, revealed a shift for both types of supplement in the balance of bacterial flora in favour of a lactobacillus type. Suppression of sensitive micro-organisms seems to be a likely explanation for the shift caused by the penicillin supplemented diet, on the other hand direct stimulation of lactobacilli by malt distillers dried solubles is a more likely explanation on the other diet.

The dominant type of lactobacillus culture was isolated from the duodenum of chicks fed with distillers dried solubles, and used in a rough microbiological assay for comparing sources of growth factors. It was confirmed that malt distillers dried solubles acted *in vitro* as a microbiological growth factor. Other feed additions such as molasses distillers dried solubles, dried yeast and dried whey acted similarly by enhancing the growth of the lactobacillus (although in varying degree), and when these additives were given to chicks, stimulation of the chick growth occurred (following communication) correlating with the microbiological test.

Further estimation of the number of lactobacillus types in the duodenal flora (by Sharpe's method⁴) showed that the increase attributable to the supplements was considerable (about 100 fold; a difference which is significant at the 1 per cent probability level) in birds receiving distillers dried solubles or molasses distillers dried solubles. Chicks and lactobacilli gave growth responses for both additives which were

roughly comparable. Further work is in progress, and it is hoped to publish a more detailed account elsewhere.

Unidentified Chick Growth Factors

The previous communication refers to a tentative microbiological assay method for certain unidentified chick growth factors, based on their growth stimulating effect on a strain of *Lactobacillus* isolated from chicks receiving distillers dried solubles in their diet. This method derives from the hypothesis that the growth factors act by modification of the microbial flora of the chick's gut.

Among materials submitted to the tentative microbial assay were fish meal, dried unextracted brewers yeast, dried whey and molasses distillers dried solubles. The latter material is obtained by vacuum evaporation and subsequent spray drying of the liquid remaining in the still following the distillation of ethyl alcohol produced by the yeast fermentation of molasses. Of these four materials only the first (fish meal) failed to elicit a marked response from the *Lactobacilli*.

Using the purified diet which has been detailed elsewhere¹, we endeavoured to confirm these findings with chicks. Eight diets, as shown, were used in an effort to demonstrate whether or not such growth factors as may be present in the various additives were the same. The chicks were housed in two electrically heated, thermostatically controlled brooders with one replicate of each diet in each brooder. Each replicate consisted of 25 Rhode Island/Light Sussex cockerels and the birds went into the units as day olds. The results obtained are given in Table 1.

There were no significant differences between diets 2, 3, 4 and the corresponding double additive diets 6, 7, 8 except that, at 4 weeks only, the mean weight increase on diet 6 was significantly higher (at the 5 per cent level) than diet 2.

Examination of the feed intake figures showed considerable differences and when the above results were adjusted to a common feed intake by the use of regression coefficients the growth response to fish meal disappeared whilst the other responses remained, albeit at a lower level. These results will be discussed

in more detail elsewhere but it appears that under our conditions fish meal acts only as a source of known nutrients (provided already in the control diet) and as an appetite-stimulating factor. On the other hand, responses are obtained to dried yeast, dried whey and molasses distillers dried solubles which are evidently due to an unidentified growth factor common to them all. It has also been established by other work including chick growth trials and the direct examination of gut flora that malt distillers solubles and molasses distillers solubles are directly equivalent in terms of unidentified growth factor activity. All these conclusions are consistent with the findings of the tentative microbial assay discussed in the communication already referred to, to which this letter is complementary.

Heterogeneity of Human Foetal Hæmoglobin: Incidence of Foetal Variants in Singapore

THREE variants of foetal hæmoglobin have so far been described primarily on the basis of electrophoretic mobility. These are known as 'Fessas and Papaspyrou' type¹, 'Bart's' type², and 'Alexandra' type³. The 'Fessas and Papaspyrou' type appears to be relatively common and reports of its incidence have so far appeared from Singapore⁴ and Indonesia⁵. 'Bart's' hæmoglobin has been identified in specimens from Texas (Dr R. Schneider) and Thailand (Dr S. Tuchinda) (Drs J. A. M. Ager and H. Lehmann, personal communication) and in one sample from Singapore.

During the period March 1958–March 1959, 2517 blood samples were obtained from the umbilical cord, at birth, of babies delivered at the Kandang Kerbau Maternity Hospital, Singapore and the British Military Hospital, Singapore and submitted to filter paper electrophoresis using a horizontal arrangement with the filter paper (Whatman 3 MM) sandwiched between glass plates treated with silicone grease.* The blood samples were collected in potassium oxalate bottles and prepared by washing twice in 0.9 per cent aqueous solution of sodium chloride, laked with a volume of water, shaken manually with half a volume of toluene and centrifuged (2500 r.p.m.) till a clear haemoglobin solution was obtained.

It soon became clear that small amounts of fast-moving and slow moving pigments (appearing as a faint yellow-coloured front and trail) were present in most samples in addition to the dark red band which contained the haemoglobins *A* + *F*. These minor fractions could be demonstrated well on staining with a protein stain (bromophenol blue) or with a benzidine reagent (pseudoperoxidase reaction) as described by Liang.⁷ The incidence of visually detectable fast and slow fractions in unstained electrophoretograms is shown in Table 1. The amount of

detected in either of the parents when these were available for study. On starch block electrophoresis the mobilities were very similar to those noted on paper.

The presence or absence of the slow or fast fractions did not appear to be related to the sex or body weight of the infant from which the blood had been obtained or to the content of alkali resistant haemoglobin (measured as described by Chernoff⁸). In a study of more than 100 children between the ages of a few days and six months who were being investigated for anaemia with or without jaundice in the Paediatric Unit of the General Hospital, Singapore, during the same period, in only one instance was a fraction (approximately 15 per cent of the total) identical in mobility with the Fessas and Papaspyrou type noted (FC 372, Figs 1 and 2). The child was treated in

Table 1 INCIDENCE OF ABNORMAL HAEMOGLOBINS IN CORD BLOOD SAMPLES IN SINGAPORE.

| Ethnic group | Number studied | Fessas and Papaspyrou type | Bart's type | Alexandra type |
|-------------------|----------------|----------------------------|-------------|----------------|
| Chinese | 1062 | 63 | 2 | 8 |
| Malay | 102 | 2 | — | 2 |
| European | 142 | 1 | — | 1 |
| Indian | 225 | 2 | — | — |
| Eurasian | 10 | — | — | 1 |
| Nepalese (Gurkha) | 10 | — | — | — |
| Total | 2517 | 68 | 2 | 12 |

fast- or slow moving pigments in these samples varied between 8 and 20 per cent of the total haemoglobin when determined by a dye-elution method, while in the two samples listed under Bart's type, the fast fractions accounted for 24–25 per cent of the total haemoglobin. In the majority of cases when insufficient amounts of fast or slow pigment were present to be detected by inspection of the wet or dried untreated electrophoretograms with the naked eye, staining with bromophenol blue or benzidine produced evidence of the presence of small amounts of these fractions. The electrophoretic mobilities of these fractions appearing on staining were very similar to those of the fast- or slow moving fractions listed in Table 1 under Fessas and Papaspyrou type and Alexandra type. At pH 8.6, on paper electrophoresis, using veronal buffer, the fast fractions had the mobility described by Fessas and Papaspyrou¹ being slower than haemoglobin *H* and a shade slower than haemoglobin *J*, while the slow fractions migrated just ahead of *E* or *A₂* and just slower than *S* or *D*. At pH 6.5, the fast fraction had a definitely anodal mobility though much less than that of haemoglobin *H*. No abnormal haemoglobins were

Fig. 1. FC 372 compared against haemoglobins *A* and *J* pH 8.6, veronal buffer. Note mobility of fast fraction, slower than that of *J*.

Fig. 2. FC 372 compared against a sample containing Bart's haemoglobin pH 8.6, veronal buffer. Note mobility of fast fraction, distinctly slower than Bart's.

hospital for severe anaemia and jaundice which developed 12 days after birth, but since his erythrocytes were found to be deficient in the enzyme glucose 6-phosphate dehydrogenase, which is known to be related to drug induced haemolytic anaemia, the anaemia can not safely be considered to be a consequence of the presence of the fast haemoglobin.⁹ It thus seems that small amounts of fast and slow moving haemoglobin fractions are present in the cord blood of the majority of new born babies and that in certain individuals for

Fig 3 Direct comparison of FC 890 against Bart's haemoglobin pH 8.6, veronal buffer

no apparent reason, the amount of these fractions may increase so as to account for up to about 20 per cent of the total haemoglobin. This picture is closely similar to that widely accepted for haemoglobin A. Normal adult haemoglobin is a heterogeneous mixture consisting of at least three variants (A_1 , the major component, A_2 and A_3 , the minor components), of which the minor components can be demonstrated on filter paper electrophoresis by staining with a protein dye⁹.

In two samples, obtained from Chinese male newly borns, a faster fraction was noted on paper electrophoresis at pH 8.6. This separated well from the main component (mixture of A and F), and had a mobility faster than that of haemoglobin J but slower than that of H. It was possible to send one of these samples (FC 890) to Drs Ager and Lehmann in London for further study. On paper electrophoresis at pH 8.6 the mobility was found to be that described above. On ion-exchange resin chromatography, the fast component moved faster than H which is the position described for 'Bart's'. Actual comparisons against 'Bart's' haemoglobin revealed the identity of the two specimens. The ultra-violet absorption spectrum of the fast component in FC 890 revealed the tryptophan fine-structure band of haemoglobin F.

A further indication that the 'Fessas and Papaspyrou' type of haemoglobin is a normal minor component of human foetal haemoglobin is obtained from the work of Fessas and Mastrolakos¹⁰. Using a starch-gel electrophoresis technique these workers have found, in all samples of cord blood studied, a well-defined zone which gives a positive pseudoperoxidase reaction, which amounts to 0.5–1.0 per cent of the total haemoglobin and which has an electrophoretic behaviour which corresponds very closely to that of the 'Fessas and Papaspyrou' type. Both this variant and the 'Alexandra' (slow-moving) haemoglobin may thus represent abnormal amounts of fractions which are normally present only in small amounts. The 'Bart's' haemoglobin may represent a truly abnormal variant of foetal haemoglobin. In electrophoretic behaviour at pH 8.6 it differs noticeably from the 'Fessas and Papaspyrou' type, in being definitely faster and having the mobility, at pH 8.6, described for haemoglobin N². It occurs at a much lower incidence, only two cases having been detected in this study and when present amounts to some 24–25 per cent of the total haemoglobin.

I am grateful to Dr H. Lehmann of St Bartholomew's Hospital, London and to Dr J. A. M. Ager of St Thomas's Hospital, London for continued interest

in this work and for help in identifying the sample FC 890 as 'Bart's' haemoglobin. Mr Stephen Pang rendered valuable technical assistance during this work.

Biosynthesis of Chondroitin Sulphates

LITTLE information is available regarding the biosynthesis of acid mucopolysaccharides. Knowledge of biosynthetic pathways to the chondroitin sulphates in particular is practically confined to the fact that glucose is utilized for both the hexosamine and uronic acid moieties¹ and that 3'-phosphoadenosine 5'-phosphosulphate (PAPS) is involved in sulphate transfer². Uridine intermediates are thought to take part by analogy to the synthesis of chitin, cellulose, and hyaluronic acid³.

This communication describes the effect of the addition of various mucopolysaccharides on the biosynthesis of chondroitin sulphate (CSA) in an isolated enzyme system.

One of the mucopolysaccharides isolated from cornea by Meyer and co-workers⁴ was the sulphate-free chondroitin, the C₄ hexosamine epimer of hyaluronic acid. They suggested that chondroitin was probably the precursor of chondroitin sulphate, the polymer being first formed and then sulphated. In a particle-free enzyme system derived from chick embryo condyles, chondroitin did not act as an acceptor of sulphur-35 labelled sulphate however⁵. This system is able to synthesise chondroitin sulphate when incubated with adenosine triphosphate and magnesium chloride².

When a partially purified sample of umbilical cord hyaluronic acid was tested in this enzyme system, strong stimulation of chondroitin sulphate synthesis resulted. Hyaluronic acid itself does not occur as a sulphate ester so that one possible interpretation of this result was that sulphation occurred at C₄ of the glucosamine moiety with inversion at this position to yield the galactosamine sulphate, namely, CSA-A. Chemical fractionation of a saline umbilical cord extract however yielded hyaluronic acid (containing protein) and a mucoprotein rich in sulphate (SMP). Stimulation of chondroitin sulphate synthesis was associated with this sulphated fraction—the hyaluronic acid fraction was without effect. The SMP had an electrophoretic mobility about half that of pure chondroitin sulphate on paper and was strongly metachromatic. When the paper was cut up into

sections, eluted and the eluates tested for stimulating power, activity was found to correspond with the metachromatic zone. After treatment of the paper electrophoretogram with chlorine followed by starch/potassium iodide, a band was evident which was superimposable with the metachromatic band obtained by staining with toluidine blue. Both reagents showed a slight zone at the origin. Free protein is then probably absent, the mucoprotein migrating as a stable covalent compound.

When SMP was digested with proteolytic enzymes a free mucopolysaccharide was obtained which was identified as CSA C ($[\alpha]_D^{20}$ Ratios hexosamine/uronic acid/nitrogen/sulphur/acetyl 1.0/1.1/0.97/0.81/1.2. The hexosamine was identified as galactosamine) (CSA C has previously been shown to occur in umbilical cords). Stimulating activity of the SMP and the CSA C were of the same order on a weight basis. CSA C isolated by enzymatic digestion of the cord residues also stimulated to the same degree (ratios hexosamine/uronic acid/nitrogen/sulphur 1.0/0.91/1.04/0.91). In addition stimulation resulted when active sulphate 3 phosphodenosine 5 phospho sulphate labelled with sulphur 35, was used as a tracer in place of sulphur 35 labelled sulphate. Activity varies with the particular enzyme extract used, the maximum degree of stimulation so far found has been 3.5 times the control.

CSA A isolated from bovine trachea by alcohol fractionation ($[\alpha]_D^{20}$ ratios hexosamine/uronic acid/nitrogen/sulphur 1.0/1.07/1.04/0.95) and further identified by its infra red spectrum, was found to have a low degree of stimulation compared to CSA C. The reality of this was born out by the fact that the more soluble alcohol fraction obtained from the preparation of the trachea chondroitin sulphate mixture, was strongly stimulating. This fraction contains the CSA C present in the cartilage and was confirmed to be a mixture of CSA A and CSA C by its infra red spectrum. Since the trachea chondroitin sulphate had been isolated by extraction with hot alkali as compared to the mild saline extraction used on the cords, CSA C was treated with alkali under the conditions used for obtaining CSA A. No loss in activity resulted.

Chondromucoprotein isolated from cartilage by the method of Malawista and Schubert⁸ was found to inhibit slightly the formation of chondroitin sulphate.

Re-extraction and reprecipitation of the counted samples led to a loss in radioactivity. This loss was about 60 per cent in the case of the controls and 40-50 per cent in the presence of added chondroitin sulphate. A broadening response above the control becomes apparent after reprecipitation. The loss of radioactivity is thought to be due to a higher solubility of radioactive chondroitin sulphate composed of shorter chain molecules as compared to the chondroitin sulphate used as a carrier. Results are summarized in Table 1.

The infra red spectrum of the mucoprotein isolated from 20-day old chick embryo condyles by high speed homogenization showed it to be predominantly CSA A with perhaps small amounts of CSA C present. Material derived from 15 day old chick embryo condyles gave a very similar spectrum the bands corresponding to CSA C being slightly more intense.

It is evident that no primer or template mechanism is involved in the biosynthesis of chondroitin sulphate. Because the enzyme system as prepared necessarily

contains relatively large amounts of mucoprotein, this probably accounts for the difference in stimulating power of CSA A and CSA C. The system being already rich in CSA A in the form of the mucoprotein. Addition of CSA C then results in a greater response than addition of CSA A if we presume that enzyme systems are present which synthesize both types of chondroitin sulphate.

TABLE 1. EFFECT OF ADDED SUBSTANCES AT EQUAL CONCENTRATION OF THE RADIO ACTIVITY OF CHONDROITIN SULPHATE FORMED BY INCUBATING A PARTICLE FREE EXTRACT OF 15-DAY-OLD CHICK EMBRYO CONDYLES WITH ALKALINE TRIPHOSPHATE AND MAGNESIUM CHLORIDE AS DESCRIBED PREVIOUSLY.¹ THE CHONDROITIN SULPHATE FORMED WAS ISOLATED BY ADDITION OF CARRIER AND PRECIPITATION WITH CETYLAL.

| Tracer | Substance Added | Radio activity of CSA relative to control as 1.0 | |
|-----------------|--|--|-----------------|
| | | Initial Precipitate | Reprecipitation |
| $Na_2^{35}SO_4$ | CSA-C Sodium salt | 1.7 | 2.9 |
| $Na_2^{35}SO_4$ | SMP Sodium salt | 1.5 | 2.3 |
| $Na_2^{35}SO_4$ | Chondromucoprotein | 0.8 | 1.0 |
| $Na_2^{35}SO_4$ | Muco-protein of chick condyles (20 days old) | 0.8 | 1.0 |
| $Na_2^{35}SO_4$ | CSA A Sodium salt | 1.3 | --- |
| $Na_2^{35}SO_4$ | CSA A Sodium salt | 1.1 | --- |
| $Na_2^{35}SO_4$ | CSA-C Sodium salt | 1.8 | --- |
| $Na_2^{35}SO_4$ | CSA C Sodium salt | 1.9 | --- |
| $Na_2^{35}SO_4$ | CSA A Calcium salt | 1.1 | 1.5 |
| $Na_2^{35}SO_4$ | CSA A + C Calcium salt | 1.5 | 2.3 |
| | 60% alcohol fraction from trachea | | |

If priming rather than template action is the mechanism involved, it must function by the alternative addition of acetyl galactosamine sulphate and glucuronic acid residues or by the addition of the preformed disaccharide or similar unit. Some evidence for the existence of a uridine derivative containing both hexosamine and uronic acid has been presented by Dorfman *et al.*⁹ When uridine diphosphoglucuronic acid was incubated with the chick condyle enzyme a suppression of chondroitin sulphate synthesis was the result.

The reason for this suppression is not clear, at the present time. Uridine diphosphoglucuronic acid has however been demonstrated to be utilized for the synthesis of hyaluronic acid by streptococci.¹⁰

A full report of this work, together with results obtained on the influence of chain length on stimulating power, will be published elsewhere.

I am indebted to Dr R. I. Cox, Dept of Veterinary Physiology, University of Sydney, for the infra red spectra.

Significance of Lactose in the Diet in Aminoaciduria caused by Maleic Acid

IN studies with rachitic rats Harrison and Harrison¹ established aminoaciduria as one of the signs of maleic acid intoxication. Angielski *et al.*² produced, by intraperitoneal administration of maleic acid, aminoaciduria in rats receiving a diet containing 50 per cent skim milk. We have studied the effect of dietary lactose on the production of aminoaciduria by maleic acid. Three groups of rats received the three diets described in Table 1.

Table 1 COMPOSITION OF DIETS (gm./kgm.)

| Component | Diet | | |
|------------------------|------|--------------|-----------------|
| | Milk | With lactose | Without lactose |
| | I | II | III |
| Dried skim milk | 480 | — | — |
| Caseln | — | 170 | 170 |
| Wheat starch | 270 | 270 | 480 |
| Sucrose | 130 | 130 | 230 |
| Lactose | — | 310 | — |
| Rape-seed oil | 88 | 88 | 88 |
| Wesson's* salt mixture | 32 | 32 | 32 |

To 1 kgm. of diet were added: 331 mgm. of a vitamin mixture⁴; 1,000 mgm. choline hydrochloride; 5 mgm. menaphthone; 150 mgm. vitamin E, 25,000 I.U. vitamin A, 2,500 I.U. vitamin D.

The rats were kept in metabolic cages allowing quantitative collection of urine uncontaminated by faeces or diet. They received unlimited food and water. Neutralized maleic acid was given intraperitoneally as a molar solution, in one dose of 400 mgm./kgm. body-weight. α -amino nitrogen was estimated in urine by the method of Yemm and Cocking⁵. The rats received their respective diets for 7–14 days before injection of maleic acid. The results are given in Table 2.

Table 2 ADULT RATS, MALES AND FEMALES WEIGHING 120–370 GM. MEAN VALUES PER RAT FOR 24 HOURS FOR GROUPS OF 5 RATS. FIGURES IN PARENTHESES SHOW THE RANGE.

| | α -Amino nitrogen (mgm.) | | |
|---|---------------------------------|---------------------|-------------------|
| | Diet I | Diet II | Diet III |
| Before administration of maleic acid (mean over 4 days) | 3.3 (1.65–5.7) | 6.2 (4.0–8.1) | 4.6 (2.5–7.5) |
| After administration of maleic acid | | | |
| Day 1 | 7.5 (5.0–9.3) | 22.5 (14.8–31.6) | 4.1 (3.4–5.8) |
| Day 2 | 10.9 (5.4–15.3) | 18.0 (15.0–22.0) | 1.7 (1.1–2.2) |
| Day 3 | 20.5 (11.5–27.5) | 37.0 (16.0–57.0) | 3.2 (1.1–7.7) |
| Day 4 | 9.5 (6.5–12.2) | 25.5 (17.3–30.5) | 7.1 (3.1–12.0) |
| Day 5 | 4.6 (2.6–9.5) | 11.8 (7.0–15.9) | 6.8 (4.0–9.4) |

400 mgm. maleic acid per kgm. body weight produced no aminoaciduria in rats on a diet devoid of lactose. Rats receiving lactose, whether from milk or as such, responded by marked aminoaciduria to the same dose of maleic acid. Maximum excretion of α -amino nitrogen was generally observed on the second or third day after administration, the values reached being five to ten times those before maleic acid was injected. After a week the excretion returned to normal again.

Maleic acid is the causative agent of the aminoaciduria but lactose seems to be necessary for its appearance.

A full report of these findings will be published in *Acta Biochimica Polonica*.

Extraction of an Actomyosin-like Protein from Human Thrombocytes

CONTINUING the work of Luscher¹, we have studied the metabolism of blood platelets in relation to clot retraction, as the latter seems to be one of the most important thrombocytic functions. Luscher² and Bounameaux³ have pointed out that in the presence of a buffered medium containing divalent cations (Mg^{++} or Ca^{++}), glucose is a factor which improves retraction. On the other hand the existence of mitochondria has been observed with electron microscopic techniques and it has been known for years that blood platelets are able to consume oxygen.

In our experiments⁴ we noticed a constant relationship between an active glycolytic system and maximal retraction capacity. This relationship does not exist for oxygen consumption. Using isolated and washed thrombocytes we were able to confirm the results of Born⁵ obtained with platelet-rich plasma. This author observed that the adenosine triphosphate level, which is very high in thrombocytes, shows a rapid fall during clotting. Also, fresh thrombocytes exhibiting maximal retraction have a high adenosine triphosphate content (about $5 \times 10^{-2} \mu$ moles/ 10^9 platelets for isolated and washed cells), whereas platelets, even if preserved at $0^\circ C$, hydrolyse their adenosine triphosphate and at the same time lose their ability to retract.

Lüscher⁶ has suggested that viscous metamorphosis is linked to the appearance of a viscous and retractile protein of complex composition, which was obtained from platelets and named 'protein S'.

In view of these facts and the results obtained by Hoffmann-Berling⁷ on undifferentiated cells, from which he isolated a contractile protein, we tried to extract a contractile protein from thrombocytes, in a way analogous to the extraction of actomyosin from muscle.

Thrombocytes from normal human blood were isolated by means of centrifugal fractionation, they were washed twice in 0.9 per cent sodium chloride containing 1% of the disodium salt of ethylenediamine tetra-acetic acid, they were washed once more with a Weber-Edsall solution (potassium chloride, 0.6 M, sodium carbonate, 0.01 M, and sodium bicarbonate 0.04 M) and after discarding the supernatant they

PHYSIOLOGY

Response of Cholinergically Innervated
Sweat Glands to Adrenaline and
Noradrenaline

were resuspended in the same medium. For a single experiment 40 ml of a suspension containing about 3.5×10^7 platelets per μ l with less than one leucocyte per 100 000 platelets, were used. This suspension was homogenized in a small refrigerated blender turning at 17,000 r.p.m. for 15 minutes. The homogenate was left overnight in the refrigerator and centrifuged for one hour at 60,000 g in order to eliminate undestroyed platelets (about 5 per cent of the initial count), cell fragments and insoluble proteins. All operations were carried out at a temperature between 0 and 4° C. The pH of the extract (13 ml) was about 7.4 and the protein content about 6.5 per cent (Kjeldahl). The extract contained some fibrinogen (clottable with thrombin) but consisted mainly of a protein which had the characteristics of actomyosin: it was soluble in a

Fig. 1. Contraction and precipitation of the actomyosin-like protein from human thrombocytes. 1-7 pictures of the same test tube taken 0-5, 1-0, 1-5, 2-0, 3-0, 5-0 and 20-0 minutes after the addition of adenosine triphosphate. The sample contains 0-25 ml. of the extract (6-4 g./ml. protein dissolved in Weber-Eisall solution), adenosine triphosphate $4 \times 10^{-3} M$, magnesium sulphate $3 \times 10^{-3} M$ water to 1-5 ml. 8 same composition without adenosine triphosphate. 9 protein solution and water only.

medium of ionic strength 0.8 and precipitated if the ionic strength was lowered by dilution with water to 0.1. If Mg^{++} and adenosine triphosphate were added to the protein at this lower ionic strength a superprecipitation or a contraction took place. After discarding the supernatants, the precipitates of the protein were readily soluble if resuspended in 0.6 M potassium chloride. The viscosity measured after the addition of adenosine triphosphate to the actomyosin-like protein in 0.6 M potassium chloride showed a significant fall as compared to the value obtained with out adenosine triphosphate. The viscosity rises again after the adenosine triphosphate has been consumed.

In conclusion a contractile protein has been extracted from normal human thrombocytes. This protein shows characteristics of muscle actomyosin and is most probably responsible for clot retraction. The conditions under which it functions during viscous metamorphosis and clot retraction are under study.

We wish to thank Dr. H. Portzehl for critical discussion and Miss M. Schneider for valuable technical assistance.

THAT the innervation of the sweat glands in the cat's foot pad is cholinergic has been recognized and generally accepted since the classical demonstration in 1934 by Dale and Feldberg¹. However, sweat droplets have been seen to appear on the foot pad following intradermal or systemic injection of adrenaline or noradrenaline, most recently by Nakamura and Hatanaka². The sweating is said to be minimal and not regularly reproducible³. In summarizing the situation, Rothman⁴ takes the view that the appearance of sweat droplets in response to adrenaline injection represents expulsion due to myoepithelial contraction, rather than secretory activity. On the other hand a dual innervation, adrenergic and cholinergic, has been postulated by Kuno⁵.

In the course of the present experiments a few droplets of sweat have been seen to appear following intravenous injection of adrenaline, but only if the ducts were filled by prior stimulation of the sudomotor nerve supply⁶. Interpretation is equivocal: there is no way of deciding from this sort of experiment whether adrenaline causes expulsion through contraction or whether it has a mild secretory action, enough to produce visible sweat if the ducts are full but not if they are empty or partly empty through reabsorption. In any event visual inspection is not a very satisfactory method for it yields information only as to sweat emergence (rather than sweat formation) which must undoubtedly be responsible for the variable results and conflicting reports in the literature.

Impedance change across the cat's foot pad is a good, although logarithmic, measure of the course of the sweat duct filling and emptying, which is to say of sweat formation and reabsorption⁷. During stimulation of the sudomotor nerves impedance falls from a high to a low value at a rate determined by the frequency of stimulation, as can be seen by comparing A and E of Fig. 1. At the close of stimulation the impedance level slowly returns to initial resting level as reabsorption progresses. After a maximal bout of activity up to 90 min are required for complete reabsorption and full recovery to resting impedance level. Injected acetylcholine produces similar changes and the effects both of nerve stimulation and injected acetylcholine are blocked by atropine, as would be expected.

Adrenaline and noradrenaline cause impedance changes similar to that resulting from acetylcholine injection. Fig. 1 illustrates an experiment in which the action of noradrenaline was examined. The cat was in nontubal anaesthesia. Stimulation was applied to the centrally covered plantar nerves which contain the sudomotor supply to the foot pads. Recording was done by means of zinc-zinc sulphate electrodes (one on the central foot pad, the other subcutaneously placed near by) an impedance bridge, the generator supplying a 20-cycle sine wave, an amplifier and cathode ray oscilloscope. Drugs were injected intravenously through the antebrachial vein.

⁷ Hoffmann-Berling, H. *Biochim. Biophys. Acta* 19 4-3 (1956).

Fig 1 Oscillographic recordings of impedance changes across the foot-pad of the cat. For each record A-E the impedance bridge was balanced initially with the sweat glands in the resting state. Width of the line indicates the degree of bridge imbalance caused by a lowering of impedance across the foot-pad. The successive lines of each lettered recording are continuous each with the next.

Record A illustrates the impedance changes due to a 10-sec electrical stimulation at a frequency of 10 per sec. There is, in the first line, a rapid decrease in impedance and a slow return toward normal which is continued in the second line. The entire recovery course in this and subsequent recordings is not illustrated. Record B presents a typical record of change following intravenous injection of noradrenaline, 40 μ gm per kilo. Lowering of impedance progresses more slowly than in A and the beginning of return toward normal is delayed indicating that the noradrenaline continues to act for some time.

Between the making of records B and C atropine, 0.5 mgm per kilo, was injected. Record C, containing the result of a 38 sec stimulation at 10 per sec, shows the effect of nerve stimulation to be completely blocked. In normal circumstances the response to the 38-sec stimulation would be enormously greater than that seen in record A. Record D, obtained immediately after record C, shows the response to a further injection of noradrenaline, 40 μ gm per kilo. Although the response is smaller than that in record B there is as yet no sure indication that atropine antagonizes the noradrenaline action⁸. Certainly, however, it is not blocked by atropine.

Record E, from another experiment, illustrates the manner in which impedance change occurs when stimulation frequency is lowered, in this case to 12 per min. Duration of this stimulation was 5 min. It is evident that response to electrical stimulation could be made to duplicate that to adrenaline or noradrenaline by careful selection of stimulus duration and frequency.

Since atropine completely blocks the effect of nerve stimulation it is unlikely that some sweat glands are adrenergically rather than cholinergically innervated. At the present time the most likely interpretation is

that all the sweat glands are cholinergically innervated, but that in addition their secreting cells are responsive to adrenaline and noradrenaline.

Coating of Red Blood Cells with Antigenic Substances

COATING of red blood cells with antigenic substances is used for titration of antibodies because the blood cells are a stable and uniform vehicle for the antigen¹⁻³. In our experiments red blood cells of sheep were first treated with tannic acid (1:20,000 in saline, pH 7.2) to stabilize them. If the solution is stronger, spontaneous agglutination takes place. The protein (bovine γ -globulin) was coated on the cell at a pH 6.4. The cells were lysed in distilled water. The cell walls were then shadowed with gold-palladium, and studied in a Siemens Elmiskop I. Fig 1 shows an untreated

Fig 1 Cell wall, untreated ($\times 10,700$)

Fig 2 Cell wall, treated with tannic acid ($\times 10,700$)

Fig 3 Cell wall, treated with tannic acid and coated with protein ($\times 10,700$)

cell wall. The surface is fairly smooth. After treatment with tannic acid the surface becomes rougher (Fig 2). Coating with protein produces a mottled appearance, and the outlines of the shadow of the edge of the cell wall are somewhat diffuse (Fig 3). It is difficult to explain these morphological changes in terms of physical and chemical processes, especially as the arrangement of the molecules on the cell surface is not fully understood. Tannic acid acts presumably as a fixative like formalin and the micrographs show that a change has taken place on a sub-microscopic scale. It is possible that the protein adheres more readily

to the rough surface. The roughening of the surface may also explain why a stronger solution of tannic acid produces agglutination of the cells. Judging by the electron micrographs it appears that the protein covers the cell wall in shapeless masses, which produce the mottled appearance.

I wish to express my gratitude to Mr. D. Dresser, Department of Zoology, University of Edinburgh, for preparing the red blood cells and also to the Melville Trust for Cancer Research who equipped the electron microscope laboratory in which the experiments were carried out.

Effect of Adrenalectomy on the Hormone Content of the Thymus in the Rat

A LARGE number of publications have dealt with the influence of the adrenal cortex on the morphology of the thymus. Adrenalectomy has been found to result in an enlargement of the thymus^{1,2}. The administration of various preparations of adrenal cortex (in large amounts) resulted in atrophy of the thymus. This was confirmed with purified cortico-adrenal extract³, cortisone⁴, dehydrocorticosterone⁴ and deoxycorticosterone⁴. The same effect could be obtained with adrenocorticotrophic hormone⁵. Since the active fraction of the thymus can be obtained in a purified form⁶ and since a minute quantity of this fraction can be bioassayed⁷, we thought it of interest to investigate the effects of adrenalectomy on the thymus by these techniques.

50 male rats of 120–160 gm were used. They were divided in groups of 5 animals and operated as follows:

(1) Bilateral adrenalectomy, three groups:

(a) Control,

(b) 200 µgm of deoxycorticosterone acetate subcutaneously daily,

(c) 200 µgm of cortisone acetate daily.

(2) Thymectomy, one group.

(3) Thymectomy, following 5 days later by adrenalectomy. The animals were autopsied 6 days after the adrenalectomy, that is 11 days after the thymectomy.

(4) Sham thymectomy and adrenalectomy. The thymus and the adrenals were removed and replaced.

Table 1. HORMONAL ACTIVITY OF THYMUS, LYMPH NODES AND SPLEEN IN THE RAT

| Group | Activity (units per gm. of fresh organ) | | |
|------------------------------------|---|------------|------------|
| | Thymus | Lymph node | Spleen |
| Normal males | 62.5 ± 5.6 | 20.0 ± 4.0 | 17.0 ± 4.0 |
| Thymectomized | — | < 6 | < 4 |
| Adrenalectomized | 33.0 | < 10 | < 6 |
| Adrenalectomized and thymectomized | — | < 4 | < 4 |
| Adrenalectomized + DOC | 79.0 | 14.0 | 10.8 |
| Adrenalectomized + cortisone | 30.4 | < 4 | < 3 |
| Sham operated | 57.4 | 22.0 | 14.8 |

without interruption of their vascular connections.
(5) The remaining 20 animals were autopsied as controls.

In every group, at autopsy, the thymus (except, of course, groups 2 and 3) the spleen and the lymph nodes (jugular and mesenteric) were pooled and extracted by the method of Bezonoff and Comas⁸. These extracts were bioassayed by the method of Comas⁷. The activity found was expressed in guinea pig units per gram of fresh organ weight.

The 20 normal animals were divided in 4 groups of 5 animals each. Thus we obtained 4 normal extracts for control.

As can be seen from Table 1, an active extract could be obtained from the normal thymus and a less-active one from lymph nodes and spleen. Yet thymectomy resulted in an important decrease in the activity of lymph nodes and spleen. Thus it can be asserted that the hormone found in these organs came from the thymus. This could also be concluded from previous experiments on guinea pigs⁹.

Adrenalectomy resulted in a decrease of the activity of the thymus to less than half the normal level. In both lymph nodes and spleen, the activity decreased too, yet it cannot be said whether this decrease was parallel, since the activity fell below measurable limits.

These effects of adrenalectomy could be prevented almost completely by repeated injections of deoxy corticosterone in normal amounts. Cortisone has no comparable influence.

The difference between the influence of deoxy corticosterone and cortisone is still more obvious if results are recalculated with a weight correction. Indeed the relative weight of the thymus in our animals was (parts per thousand):

2.5 ± 0.3 in normal rats

3.3 ± 0.5 in adrenalectomized rats

5.4 ± 0.6 in adrenalectomized rats treated with deoxy corticosterone

3.2 ± 0.4 in adrenalectomized rats treated with cortisone

Thus, for the total activity of the thymus in every group, we have

In normals 23 units per 100 gm. living weight

In adrenalectomized

15 units per 100 gm. living weight

In adrenalectomized deoxycorticosterone treated

35 units per 100 gm. living weight

In adrenalectomized cortisone treated

14 units per 100 gm. living weight

It can be concluded that the hormonal activity of the thymus is conditioned by the adrenal cortex to a large extent. This influence of the adrenal cortex upon the thymus is supported by the deoxy corticosterone fraction. In other words, it seems to be connected with the mineralocorticoid and prothymogenic effects of the adrenal cortex.

I am grateful for the technical assistance of A. Moser.

Quantitative Changes in γ -Aminobutyric Acid Induced by Low Temperature in Rice Plants

AMONG the free amino-acids occurring in higher plants increasing attention is being paid to γ -aminobutyric acid, although it has not been identified as a constituent of proteins. The significance of this compound in the nitrogen metabolism of plants is clearly indicated by the work of Steward and collaborators^{1, 2}, and also by our recent studies on rice varieties exhibiting various degrees of resistance against the 'browning disease' of rice ('*brusone*,' '*aki-ochi*')

Our experimental material consisted of the brusone-resistant *Precoce Allorio* and brusone-susceptible *Dunghan Shali* rice varieties. The experiments were carried out in the field on limeless soils. The shoots of rice plants were removed shortly after flowering, the exudate yielded by guttation was collected and analysed for free amino-acids by paper chromatography³ in a solvent system containing butanol, acetic acid, and water in the proportions 2:1:1. γ -Aminobutyric acid was not detected in the exudate of *Dunghan Shali* (susceptible variety) for some days after a period at a low temperature (12–14°C) and of unfavourable light relation. A similar decrease in γ -aminobutyric acid did not occur in *Precoce Allorio* which is regarded as a variety resistant to brusone. The content of γ -aminobutyric acid of both varieties was similar and constant in rice plants kept at normal temperatures (20–22°C). The experiments were repeated several times with the same results (Fig. 1).

When, due to bad weather, the temperature of the inundation water and of the soil drops, the incidence of disease is higher. Therefore, low temperature is regarded as one of the main factors increasing the susceptibility of rice plant to brusone⁴. It seems possible that the detection of resistant varieties by

means of some chemical characteristics will yield a reasonable tool which might substitute the long and empirical work of plant breeders.

BIOLOGY

Plastron Respiration in the Eggs of *Drosophila* and other flies

It has long been known that the conspicuous projections near the anterior end of the eggs of *Scopeuma*, *Drosophila*, and other flies are concerned in respiration, and the projections have been called respiratory horns. The site of entry of oxygen into the horn has not previously been determined, but where not explicitly stated it has been implied that oxygen enters through holes in the distal end of the horn. Reaumur¹ regarded the respiratory horns of *Scopeuma* as floats that served to prevent the submergence of the eggs and so their asphyxiation. A similar function has been postulated for the respiratory horns of *Drosophila* by Wigglesworth and Beament². However, the eggs of *Scopeuma stercorarium* L. and *Drosophila melanogaster* Meig., as well as those of many other species with similar respiratory horns, are heavier than water even when the chorion and plastron are air-filled and besides are normally stuck to the substrate: they do not float if submerged, when under natural conditions they might be washed away from the larval food supply. Portions of cow pats containing eggs of *Scopeuma* and *Hebecnema umbratica* Meig. were repeatedly submerged in water, but the eggs were never detached. Of course these eggs and those of *Drosophila* and other species can be suspended from the surface film if they are freed from their attachment to the substrate and a line of contact with the water and air is established. Under these conditions their centres and buoyancy and gravity are such that the tips of the respiratory horns often project above the surface film.

The term plastron has been restricted to describe a gas film of constant volume and an extensive water-air interface. Such films are held in position by a system of hydrofuge structures and are capable of resisting water under pressure. In well-aerated water a plastron enables the insect to remain immersed indefinitely, when it obtains the oxygen it requires from the ambient water. What was known of plastron respiration in insects was summarized by Thorpe³ in 1950. Since then the plastron method of respiration has been found in a variety of insect pupae^{4, 5} and now in the eggs of *Sepsis violacea* Meig., *Drosophila melanogaster* Meig. and other species of the genus, *Musca autumnalis* Deg., *Hebecnema umbratica* Meig., *Scopeuma stercorarium* L., and other flies.

A detailed account of the structure of the respiratory horns of the eggs of *Drosophila*, *Scopeuma* and other flies will be published elsewhere. In all the

1, leucine, 2, valine, 3, γ -aminobutyric acid, 4, alanine, 5, glutamic acid, 6, aspartic acid + serine + glutamine, 7, histidine + arginine, 8, cyst(e)ine.

surface of most of the respiratory horn consists of an open hydrofuge meshwork that provides a large water air interface, as shown in Figs 2 and 3. At the base of the respiratory horn the air in the plastron meshwork is continuous with the air film contained between the vertical columns connecting the inner and outer laminae of the chorion (Fig. 4). Wigglesworth and Beament² claim that in *Drosophila* the air is contained in the vertical columns and not in the spaces between them. This claim is based upon the appearance of eggs injected with cobalt sulphide. When dipterous eggs are heavily injected with sulphide, the sulphide fills the spaces between the columns, but when they are lightly injected the sulphide adheres to the surface of the columns so that at first sight the columns themselves appear to be impregnated with the sulphide. The vertical columns of the chorion do not contain air in any of the dipterous eggs examined by me (Syrphidae, Sphecidae, Sepsidae, Drosophilidae, Muscidae, Cordulidae).

Fig. 1. Egg of *Drosophila gibberosa*, a species with two pairs of respiratory horns. Fig. 2. Part of a longitudinal section of the larger respiratory horn of *Drosophila gibberosa*. Fig. 3. Surface network of part of apical half of respiratory horn of *Drosophila gibberosa*.

Fig. 4. Section through chorion of *Drosophila melanogaster*.

Besides having a sufficient surface area, if a plastron is to be an efficient respiratory adaptation it must resist both wetting at pressures to which it is normally subject in nature and loss of water proofing from surface active materials. It was found that the plastron of many species of flies (*Sepsis*, *Drosophila*, *Musca*, *Hebecnema*, *Scopema*) resists in water a hydrostatic pressure of 3 feet for more than 24 hours, and the plastron of some species of *Drosophila* resists an excess pressure of 1 atmosphere for over 30

minutes. The plastron of none of the three species is wetted even when the contact angle is reduced by surface active materials to 50°–55°, which corresponds to a reduction of the surface tension of water to about 25 dyne/cm.

Insects with a plastron are restricted to well aerated waters such as rapidly flowing streams since a plastron is also a means of extracting oxygen from the tissues if the oxygen pressure of the environment falls below that of the tissues. The plastron method of respiration therefore seems unlikely to be found in an environment such as relatively fresh cow dung, where reducing conditions probably sometimes occur. However, the respiratory horns bearing the plastron project above the crust of the cow pat and provide a direct route for the entry of oxygen into the layer of air held beneath the relatively impermeable chorion. The significance of the plastron immediately becomes apparent when cow pats are observed in the rain: when it rains a rapidly moving and well aerated layer of water flows over the cow pat and over the respiratory horns. The incubation period of the eggs of *Scopema* and *Hebecnema* is only two to three days and thus in a rainy period much of the incubation period may be passed beneath a layer of water.

The respiratory horns of dipterous eggs are adapted both for the extraction of oxygen dissolved in the water and for atmospheric respiration. In water they provide a relatively enormous surface area for diffusion, and their structure is such that they do not collapse under the hydrostatic pressures to which they are normally subject. When the egg is not covered with water, the respiratory horns do not involve water loss over an enormous surface area because the connection between the plastron and the layer of air in the chorion is relatively restricted. The respiratory horns of dipterous eggs are thus structures that enable the immobile eggs to meet the contradictory demands presented to them by environments that are alternately dry and flooded.

A Seasonal Sex Difference in the Infestation of Rabbits with the Nematode *Trichostrongylus retortaeformis* (Zeder, 1800)

LARGER numbers of nematodes in male than in female hosts have been recorded for *Ascaridia galli* in chickens¹ and for *Aspiculuris tetraptera* in mice², with *Syngamus trachea* in partridges, on the other hand, infestations are more severe in females than in males.³ The present results, relating to *Trichostrongylus retortaeformis* in European wild rabbits, *Oryctolagus cuniculus* (L.), are of interest in indicating a seasonal change in host resistance: males being more resistant in summer and females in winter.

The abundance of *T. retortaeformis* was studied in 1072 rabbits collected during one year at Gwavas Forest some 30 miles south west of Napier in the North Island of New Zealand; supplementary samples (Table I) were obtained from Gwavas and elsewhere in

subsequent years. Worm abundance was assessed by a dilution-sampling technique⁴, the values obtained and shown in Fig 1 and Table 1 represent one tenth the number of worms present.

Fig 1 illustrates monthly variations in the mean number of worms in full-grown (> 900 gm paunched weight) male and female rabbits collected at Gwavas during 1950-51. During March-September, levels of infestation were higher in males than in females, but this relationship was reversed during October-February, a period that covers the middle and end of the rabbits' breeding season. The differences between the sexes were statistically significant at the 5 per cent level in June, July and in early August, when males had the higher infestations, and in December and in January, when females were the more heavily infested. The supplementary samples from Gwavas and elsewhere in other years (Table 1) conform to the general pattern found at Gwavas in 1950-51, males having the higher infestations in winter and females in summer. The seasonal changes illustrated in Fig 1 are therefore both regular and widespread.

Rabbits of both sexes frequently graze over the same ground, so it is unlikely that females ingest substantially more worm larvae than do males in

summer or that males ingest more than females in winter. The differing levels of worm infestation are therefore interpreted as due to differences in host resistance rather than as due to differences in the host's opportunity to acquire infestation.

In districts where *T. retortaeformis* is abundant, the presence of adult rabbits with no worms other than infective larvae indicates recent self-cure⁵. At Gwavas in 1950-51, the proportion of uninfested male rabbits was much higher from October to December (17 per cent) than in the preceding or following 3-month periods (0 and 4 per cent respectively), and this implies that self-cure was important in causing the rapid decline in the level of infestation in male rabbits in October (Fig 1). Only 2 of 52 female rabbits showed self-cure during the period October-December. It is concluded therefore that the March-September trend towards high levels of infestation was terminated in October by the onset of self-cure in male rabbits and that some factor prevented self-cure in females. The October sample contained only 13 female rabbits and the apparent low level of infestation is probably fortuitous, since, unlike the males, the females were heavily infested again in the following months.

In young females (900-1100 gm paunched weight), infestations were higher in pregnant than in non-pregnant animals, the difference being significant at the 1 per cent level. Sex of host had little effect on the abundance of *T. retortaeformis* in sexually immature rabbits (< 900 gm paunched weight). It seems therefore that the high levels of infestation in female rabbits in summer is associated with pregnancy. A comparable situation occurs in sheep where a rise in nematode egg counts is associated with pregnancy and lactation⁶.

It is difficult to explain why male rabbits are more heavily infested than females in winter. The establishment of *Cysticercus crassicolis*⁷ and the growth of *Hymenolepis diminuta*⁸ in rats were favoured by male sex hormones, and something similar may occur with *T. retortaeformis* in rabbits, the effect being masked in summer by the lowered resistance of pregnant and lactating females.

The differing levels of worm infestation shown in Table 1 are due to two main factors: sex of host (involving differences in host resistance only) and locality of collection (involving differences in host resistance and in the availability of worm larvae, the latter resulting from variations in climate, vegetation and host density). It is interesting that the sex-linked differences in levels of infestation are as great as the locality-linked ones even though the localities differed widely in climate, vegetation and density of rabbits. This emphasizes the importance of density of rabbits in determining levels of nematode infestation in wild animals. The present results indicate the necessity of recording sex of host in parasitological studies involving wild or laboratory animals.

Sodium Regulation in the Blood of Parr and Smolt Stages of the Atlantic Salmon

THE seaward migration of the salmon (*Salmo salar*) which coincides with the parr smolt transformation involves the solution of important osmotic and mineral regulation problems by the fish. The lack of tolerance for salt water at the parr stage has been noted previously.¹ However neither the capacities for mineral regulation of this stage nor their probable shift in the smolt have been subjected to an analysis made more desirable by the fact that, like the endocrinological changes which occur at the same time² they may be causally connected with migration itself.³

Working at Laholm in the South of Sweden we were able to investigate the regulation capacities for sodium of the young salmon in the parr stage as well as those of one and two year-old smolts reared under the same conditions in running water of the Lagan stream. Moreover an opportunity arose which allowed us to conduct simultaneously similar experiments on individuals migrating downstream captured in the nearby Ätran stream in water having the same temperature (0.3°C). The blood plasma of the animals in 10 λ quantities was subjected to micro sodium analysis by means of flame spectrophotometry.

When abruptly transferred from fresh water to full sea water (at the same temperature) none of the two year-old parrs survived for more than 26 hours. The living individuals analysed showed, as time went on, a rapidly rising sodium concentration in their blood. None of the individuals in the smolt stage whether one or two year-old died when submitted to the same abrupt change in salinity. The sodium concentration in their blood remained nearly constant in the days following the transfer. The smolts trapped on their downstream migration still showed parr characteristics to a certain degree. Two out of ten died within 18 hours when abruptly transferred to sea water. A further three showed great distress. The sodium level in the blood of the surviving individuals increased strongly, the normal level being however restored 4-5 days later. Obviously they were in a transitory condition which also includes the sodium regulation of their blood. Similar results were obtained in other experiments.

Fig. 1. Variations of the sodium concentration of the blood after abrupt transfer from fresh water (0.3°C) to full sea water (0.3°C). +, two-year-old parr; O, two-year-old smolt; Δ , wild smolt caught on downstream migration.

It has been observed in Hölle during the parr smolt transformation that a large percentage of the smolts die when kept back in fresh water. The osmotic capacities of the smolts in fresh water seem to be impaired at the time when the parr smolt transformation occurs. Wide individual variation in the sodium level of wild smolts in fresh water is obvious from Fig. 1. Details of this and previous work will be published elsewhere.

Release by Flight Exercise of a Chemotropic Response from Photopositive Domination in a Scolytid Beetle

ONE of the remarkable features of bark beetles and ambrosia beetles is their power of discovery and selection of host tree material. From a mass of varied material in a forest they select and bore into specific parts of specific trees usually only when those trees are under stress of age, environment injury or encroaching death. Certain of the ambrosia beetles show a strong preference for logs that have 'ripened' for a period of some weeks or months after being felled. The species *Trypodendron* (*Trypodendron*) *lineatum* Oliver (Scolytidae), is one of these.

The present communication is a preliminary report on an aspect of behaviour in *T. lineatum* that appears to be a key to elucidating the host finding process in this insect and perhaps other Scolytids.

Trypodendron, on issuing from its overwintering quarters in the litter of the forest floor, takes to flight and arrives in large numbers at partly 'ripened' logs of coniferous species. It appears to accomplish this result without expending time and effort on unsuitable material. Theoretical considerations of the known physiology of trees and behaviour of insects, suggested that odour must be examined as a possible clue that these beetles use in host discovery and selection. Studies were undertaken to determine whether they show any kinetic or directional response to airborne odours from attractive wood. Many failures under illuminated conditions to detect decisive or even statistical differences of activity in beetles exposed to wood odour led to the conclusion that the failure lay not in the environmental conditions nor in the method of observation, but in the photic orientation responses that dominated behaviour at a particular time. This conclusion led to the search for a natural

but in tonic smooth muscles the diameter is very variable (150–1000 Å in *Mytilus*, 150–500 Å in *Gryphaea*). This range of diameters is seen in the cross section of any fibre and may simply be due to variations between filaments. An alternative explanation is that the filaments are discontinuous along the fibre each filament has the shape of an elongated spindle, and (these being smooth muscles) the filaments are not transversely aligned.

There are large numbers of thin filaments (Fig. 1) and bridges link them to the thick ones (Figs. 2, 3). The axial spacing of the bridges is about the same (100–200 Å) as in similarly prepared sections of striated and *Loligo* muscles (see electron micrographs in refs. 1 and 2). Again as in striated muscles the bridges may belong to the thick filaments, for in preparations of the oyster muscle from which all the thin filaments have been extracted (by a fixative containing too little salt) bridges can be seen on the thick filaments.

Fig. 1. *Gryphaea* transverse section. Fig. 2. *Gryphaea* longitudinal section. Fig. 3. *Mytilus* longitudinal section (Scale: 1000 Å).

Evidence that the thick filaments in the *Mytilus* muscle do not shorten when the muscle shortens comes from measurements which were made of their diameters in equivalent fibres in pairs of muscles which had been fixed at different lengths. Although the short muscles were as little as one third the length of their partners, they showed no differences in filament diameters or in the relative numbers of filaments in each size category. (It should be noted that the filaments are thick enough to be measured sufficiently accurately.) These thick filaments therefore do not shorten and they must be discontinuous along the fibre. There is ample evidence that they remain straight and parallel to the fibre axis. Secondly, it was argued that if the thick filaments were continuous from one end of the fibre to the other, and contracted then transverse sections through stretched and shortened fibres should show considerable and predictable differences in the numbers of filaments per unit area: thus a fibre with an initial cross sectional area of a would, after shortening

by 60 per cent show the same number of filaments distributed over an area of $2.5a$ if the fibre remained at constant volume. Making such a comparison we find that there is in fact no consistent difference in the numbers of filaments per unit area in long and short muscles, and never a difference on the scale predicted. All these results support the view that the thick filaments are discontinuous and do not contract, but instead change their positions as they slide. Whether or not this is also true of the thin filaments is still an open question. But we have observed in transverse sections through extended fibres of the oyster muscle that the thin filaments are absent around the thickest of the thick filaments but present around the others: in shorter fibres all the thick filaments are surrounded by thin ones. This could mean that the thin filaments are discontinuous and, in an extended muscle do not reach as far as the middle (thickest) part of the thick filaments: a state of affairs which would be comparable to that in the H zone of a striated muscle.

By analogy with the contractile mechanism in striated muscles it could be assumed that in these tonic smooth muscles of lamellibranch molluscs the tension developed during the active state is due to the formation of linkages between thick and thin filaments. The next problem will be to explain in structural terms the observation that in such smooth muscles the decay of tension can be two orders of magnitude slower than that of the active state: their capacity for prolonged tonic contraction may well be due to this extremely slow decay of tension.

The muscles were held taut at a defined length and extracted with water glycerol, then equilibrated with 0.1 M potassium chloride at pH 6.8 and fixed at 0°C for 1 hr in a 1 per cent osmium tetroxide solution buffered at pH 7.0 or 7.4 and containing 0.4 M sodium chloride (approximately isosmotic with sea water). After additional staining with phosphotungstic acid (in 100 per cent ethanol) the fibres were embedded in Araldite and sectioned. Similar results were obtained when living muscles were prepared by the same method: but the removal of material soluble in water glycerol greatly clarified the appearance of the contractile apparatus.

We understand from Dr. Andrew G. Szent-Györgyi that a paper describing the presence of two kinds of filaments in tonic smooth muscles of lamellibranch molluscs has been submitted for publication in the *Journal of Ultrastructure Research* by Philpott, Kahlbrock and Szent-Györgyi.

ENTOMOLOGY

Relationship between Larval and Pupal Periods of some Lepidopterous Insects

EXPERIMENTS have been carried out in the United Kingdom and the United Arab Republic (Egypt) to show the effect of population density on the silver Y moth, *Plusia gamma* L and the cotton leaf worm, *Prodenia litura* (Fab) respectively. In these experiments two parallel cultures of solitary and crowded conditions were maintained for each species.

When discussing the results obtained, an interesting phenomenon attracted our attention. That is, a negative relationship exists between the larval and pupal periods of each species irrespective of sex and culture. In other words, the longer the larval period, the shorter the pupal period and *vice versa*. This phenomenon occurred in both solitary and crowded cultures as shown in Fig 1. Results also showed that the larval period was longer in the solitary culture than in the crowded culture, while the opposite occurred in the

differences between solitary and crowded conditions for larval and pupal periods were significant.

It has been found that crowding accelerated pupation by the shortening of larval period of some Lepidoptera¹ and this was probably due to competition in the crowded culture. Accordingly, it may be suggested that the longer pupal period in the crowded condition and the shorter period in the solitary treatment might be a result of the negative relationship between the larval and pupal period. However, explanation of the nature of this negative relationship implies the need for further physiological investigations of both larvae and pupae of each culture.

Possible Role of Glycerol in the Winter-Hardiness of Insects

DURING investigations into the carbohydrases of insects¹ in the winter of 1957-58 it was found that the macerated tissue of the dormant larvae of the wood-boring insect of the species *Melandrya striata*, found in felled wood of *Saxx amygdaloides* Anderss, contained a considerable proportion of glycerol as revealed by paper chromatography. This preliminary obser-

vation indicated that glycerol might be acting as an anti freeze² a view supported by the observation that the larvae and the adult insects of *M. striato* did not contain glycerol during summer

The dormant black carpenter ants (*Camponotus pennsylvanicus pennsylvanicus* var.) and their eggs found in Minnesota have now been shown to contain, in winter time, about 10 per cent of glycerol based on the weight of the dormant ants, the water content of the dormant ants was 55 per cent. Chromatographic analysis also indicated that the ants contained glucose and an unidentified oligosaccharide, whereas the eggs contained no such compounds. The same species of ants in an active state obtained in November, 1958, from Maryland contained glucose and fructose but no glycerol. That the glycerol is probably playing a major part in the winter hardiness of this species of carpenter ants is indicated by the observation that when the Minnesota ants were brought out of their state of dormancy by slowly allowing them to attain room temperature (20-25°C), they became active and, after about three days, glycerol could no longer be detected in their macerated tissue. When the ants were returned to the dormant state, by cooling them slowly and keeping them for about 6 days at 0-5°C, glycerol was again found to be present in their tissue. We have taken the Minnesota ants out of, and returned them to, a state of dormancy 3 times by alternate warming and cooling. During induced dormancy the ants always contained glycerol and each time they resumed an active state the glycerol disappeared.

The glycerol was isolated from the Minnesota ants and from their eggs by extracting the macerated tissue with methanol. After purification by sheet paper chromatography, using pyridine/ethyl acetate/water (2:5:7) as the solvent, the glycerol readily formed a tri p nitrobenzoate, m p and mixed m p 196° (after recrystallization from acetone).

The active ants from Maryland seemed to show some resistance to induced dormancy by cooling since they showed slight movement even at 0 to 5°C whereas the Minnesota ants, treated in the same manner, were motionless. Nevertheless after keeping the Maryland ants at 0-5°C for 30 days they contained glycerol.

The dormant larvae of the European corn borer (*Pyrausta nubilalis*) have also been found to contain glycerol.

Although glycerol may well play a major part in the winter hardiness of insects it is evidently not the only agent which enables insects to survive the effects of freezing temperatures for we have found that the larvae of the wood boring insect *Porandria brumnea*, and those of *Osmoderma crenicollis*, do not contain glycerol.

It is of some interest to note that the finding of glycerol in insects offers a biological analogy for the technique of preserving bone marrow and semen in glycerol at low temperatures.

We are grateful to Mrs. Hewitt Fletcher, Sandy Springs, Maryland for a supply of notho carpenter ants. We also thank Dr. E. F. Cook, Dr. A. C. Hodson and Dr. F. G. Holdaway, Department of Entomology, University of Minnesota, for their assistance and interest in this work, and the U.S. Department of Agriculture for their support.

Mode of Egg Laying in Tingidae (Hemiptera)

According to Imms¹ tingid bugs insert their eggs into plant tissue. Patel and Kulkarny², who studied the hibernation of the brinjal tingid, *Urentius echinus* Dist., and Sharga³ and Samuel⁴ who studied the egg laying habit of *Monanthio globulifera* Wlk., merely state that the eggs are inserted into the leaf tissue, none of these workers describes the actual way in which the eggs are thrust into the plant tissue and what precedes the deposition of eggs. The purpose of the present communication is to describe an apparently unknown series of actions on the part of the female tingid, culminating in the deposition of an egg, which is invariably preceded by extensive probing and actual marking by the rostrum.

The tingids included in the present study are *Galeatus* sp. on *Borlaria cristata* *Urentius echinus* Dist. on brinjal and *Monanthio globulifera* Wlk. on *Coleus* sp.

The three species insert their eggs into the tissue of tender portions of their host plants. The ovipositor is well developed dagger shaped and pointed at the tip. While ovipositing, the female bug in all these species follows a very uniform procedure, the exact significance of which is not clearly understood. Before depositing an egg, the female moves about on the surface of the leaf or tender twig all the time probing by means of the tip of her rostrum, and occasionally even inserting the stylets into the plant tissue and drawing them out. Finally, perhaps on finding a suitable site for egg laying the whole length of the stylets is driven deep inside the plant tissue.

With her stylets still inside the plant tissue the female moves her body forward by changing the inclination of the legs, which were formerly inclined backwards and now lean forwards carrying the body with them. Then the stylets are withdrawn from the plant tissue, apparently with some difficulty. The ovipositor, as a whole is slowly drawn out from underneath the abdomen so that it almost assumes a position perpendicular to the abdomen. The tip of the ovipositor begins probing, obviously in search of the puncture made by the stylets, in order to insert an egg, and unless the bug locates this puncture with the tip of the ovipositor she does not lay an egg, and moves on to find another suitable place. The ovipositor is inserted through the same puncture and the entire length is driven into the plant tissue. Next a series of alternate distentions and contractions of the abdomen and a sort of pumping action culminate in the deposition of an egg and immediate withdrawal of the ovipositor from the plant tissue. During the process of egg laying the abdominal tip is very near the surface of the plant and the body is inclined at 30° to the plant surface.

The opercular end of the egg is just visible at the surface of the plant. The entire process from probing with the rostrum to the withdrawal of the ovipositor takes 3-4 minutes.

The significance of the rostrum in oviposition in these tingids is not clearly understood.

Further work on the egg laying habit in different forms of the group and the significance of this process is being pursued.

PATHOLOGY

Aneuploid Deoxyribonucleic Acid Content of Human Carcinomas

THE basic question of whether primary human malignant tumours consist of euploid or aneuploid cells has so far remained unanswered. It has been possible to determine the chromosome complement and deoxyribonucleic acid content only of human carcinomas with cells exfoliated in ascitic fluid^{1,2}, human carcinomas transplanted in rats and hamsters³ and carcinomas grown in tissue culture^{4,5}. This lack of information can be attributed to several technical difficulties. Chromosome counts on solid human tumours cannot be generally obtained since a pre-treatment with colchicine is impossible. The deoxyribonucleic acid measurement by the one-wave-length method has so far been limited to interphase nuclei⁶ in which the occurrence of deoxyribonucleic acid synthesis prevents any conclusions in regard to euploidy or aneuploidy.

This difficulty in interpreting the deoxyribonucleic acid data can be eliminated by selecting metaphases, anaphases or early telophases for the deoxyribonucleic acid determinations. The deoxyribonucleic acid content of these mitotic stages can be considered to yield the basic amount, since synthesis is completed before the cells enter mitosis. By choosing metaphases and telophases the deoxyribonucleic acid content of dividing cells is revealed. This eliminates the criticism that the observed abnormal values are limited to dying cells of necrotic areas, which do not contribute to the growth of the tumour.

The two-wave-length method of Patau has been applied for the deoxyribonucleic acid determination⁷. Each nucleus was measured twice. The average values are given in Fig. 1. Lymphocytes or polymorphs present in the same section as the tumour cells were used to obtain the deoxyribonucleic acid value of a diploid cell. The accuracy of the method applied becomes evident by comparing the ratio between lymphocytes and normal epithelium in metaphase and telophase, and between such metaphases and telophases. The ratios expected theoretically are 1.2, 1.1 and 2.1, respectively. The values actually obtained are in close agreement with the theoretical ones, namely 1.202, 1.099 and 2.1.

Fig. 1 The deoxyribonucleic acid content of telophase nuclei (solid) and of metaphase plates (outlined) of normal epithelium and adenocarcinomas of breast, bronchus and large intestine. The diploid amount of deoxyribonucleic acid is given by the interphase nuclei of lymphocytes. 1, Lymphocytes; 2, epithelium; 3, breast carcinoma; 4, bronchogenic carcinoma; 5, intestinal carcinoma.

The distribution of deoxyribonucleic acid in the cell population of lymphocytes, of normal intestinal epithelium and of carcinomas of bronchus, breast and large intestine is shown in Fig. 1. All three carcinomas consist of cells with aneuploid amounts of deoxyribonucleic acid. The deoxyribonucleic acid content of the breast carcinoma cells accumulate around a hexaploid value and the carcinoma of the intestine around a hyperdiploid modal value, whereas the deoxyribonucleic acid values of the bronchogenic carcinoma cells are scattered over a wider aneuploid range. The deoxyribonucleic acid content of the early telophases exhibits in both the carcinomas of the breast and bronchus a narrower range as compared with the values of the metaphase plates. This indicates that several of the aneuploid cells are unable to finish the mitotic cycle, a conclusion which is supported by the results obtained on human ovarian tumours⁸.

Cells with aneuploid deoxyribonucleic acid contents have so far been found in 25 carcinomas of the large intestine⁹, in 4 carcinomas of the stomach⁹, in 5 carcinomas of bronchus and 5 carcinomas of the breast. The aneuploid modal value and the spread of the deoxyribonucleic acid values around this value varies from tumour to tumour. No correlation between a particular aneuploid deoxyribonucleic acid amount and histological grade of malignancy has been observed. The only difference found so far was between benign polyps and adenocarcinomas of the intestine, the former having a normal diploid and the latter having an aneuploid deoxyribonucleic acid content⁹.

The results obtained on different carcinomas of man demonstrate that primary malignant epithelial tumours regularly consist of cells with an aneuploid deoxyribonucleic acid content. The aneuploidy of the viable dividing cells is clearly demonstrated by the presence of aneuploid deoxyribonucleic acid contents in metaphases as well as in anaphases or early telophases. It can be concluded therefore that primary carcinomas of man are aneuploid and that the results

obtained on ascites fluids^{1, 2} or on grafted tumours³ are comparable to the conditions present in the tumour of origin

Effect of Bacillus Calmette-Guérin Infection on Transplanted Tumours in the Mouse

DURING the growth of certain transplanted tumours considerable hyperactivity of the reticulo endothelial system is observed.¹ Similar alterations are also found in the first stage of experimental infections suggesting that the host response to foreign tissue and some infectious agents is closely related. Agents such as endotoxins, zymosan, products of the tubercle bacillus, and Bacillus Calmette Guérin infection which enhance the activity of the reticulo endothelial system² and the capacity for antibody production³ also increase natural resistance to infection.⁴ In light of these observations, we have attempted to alter the growth and lethality of various experimental tumours by agents known to possess the common property of stimulating the phagocytic capacity of the reticulo endothelial system. One such agent, zymosan, has been demonstrated to increase significantly the regression rate of the mouse tumour sarcoma 180 (S 180) under certain conditions.⁴ The present report deals with the course of three transplantable tumours, S 180 carcinoma 755 (Ca 755), and Ehrlich ascites in mice infected with Bacillus Calmette Guérin.

Young, female Ha/ICR Swiss mice and C57 hybrid mice (bred by Dr J. J. Bittner, University of Minnesota) weighing approximately 18–20 gm., were injected intravenously with one mgm. Bacillus Calmette Guérin wet weight. The Bacillus Calmette Guérin (Phipps strain) was grown in either Santon's (supplied through the courtesy of Mr H. J. Henderson Phipps Inst., Phila Pa) or the Dubos liquid medium. Neither morbidity nor mortality attributable to Bacillus Calmette Guérin infection alone was observed. Infected animals appeared active and perfectly healthy. At selected intervals following Bacillus Calmette Guérin inoculation infected animals and appropriate controls were challenged with either solid tumour (S 180, Ca 755) implanted subcutaneously or by intraperitoneal injection of Ehrlich ascites cells.

Growth of S 180 in normal Ha/ICR Swiss mice is characterized by death of 85–90 per cent of hosts in two to five weeks, the remainder of the mice undergo spontaneous regression of their tumours. The effect of Bacillus Calmette Guérin infection on the mortality associated with growth of this tumour is presented in Table 1. In mice implanted with S 180 one day

Table 1. MORTALITY FOLLOWING S 180 IMPLANTATION

| Controls | Days between B.C.G. infection and tumour inoculation | | | | | |
|----------|--|------|------|------|-----|-----|
| | 1 | 7 | 14 | 19 | 25 | 67 |
| 68/70† | 13/15 | 3/12 | 0/12 | 0/30 | 0/5 | 0/0 |

† mortality/number per group

following infection the regression rate was normal whereas mice inoculated with the tumour seven days, or longer, after Bacillus Calmette Guérin infection showed definite protection. Of the groups at seven and nineteen days post infection, 70–75 per cent of tumours regressed. Mice inoculated with S 180 fourteen, twenty five, and sixty seven days following Bacillus Calmette Guérin infection were completely resistant to tumour growth. The tumours in Bacillus Calmette Guérin infected animals developed normally for the first seven to ten days and then began decreasing in size after the second week. The process of regression in animals infected with Bacillus Calmette Guérin was essentially similar to that observed in the few control mice which rejected their tumours. In a group of C57 hybrid mice implanted with S 180 fourteen days following Bacillus Calmette Guérin infection only one out of eight animals regressed. The implanted tumour, none of the tumours in the control animals regressed. The finding that C57 hybrid mice responded poorly to S 180 inoculation at a time when Swiss mice were completely protected correlates well with our unpublished observation that the C57 hybrid does not attain as high a degree of reticulo endothelial stimulation as Swiss mice following Bacillus Calmette Guérin infection.

Fig 1 demonstrates the altered course of the Ehrlich ascites tumour in *Bacillus Calmette-Guérin* infected Swiss mice. The average survival time in uninfected controls was 14 days. In animals inoculated with *Bacillus Calmette-Guérin* eleven or thirteen days previously, it was 27 days. Ascites formation in infected animals was not inhibited, in fact, during the course of the enhanced survival time, these animals frequently developed hugely distended abdomens. Despite the presence of appreciable quantities of ascitic fluid, the infected animals remained healthy and active for a longer period than their corresponding controls.

Table 2 *Ca 755* IMPLANTED 17 DAYS FOLLOWING *Bacillus Calmette-Guérin* INFECTION IN C57 HYBRIDS

| | Average tumour diameter (cm) | | Per cent mortality B C G /Controls |
|---------|------------------------------|-------------------|------------------------------------|
| | 13 Controls | 10 B C G Infected | |
| 25 days | 2.04 | 0.82 | 0/0 |
| 33 days | 2.68 | 1.21 | 0/23 |
| 48 days | 3.56 | 2.39 | 0/92 |

B C G—*Bacillus Calmette Guérin*

Table 2 summarizes the results of experiments concerned with the growth of *Ca 755* in both normal and *Bacillus Calmette-Guérin* infected C57 hybrid mice. In addition to the slower growth of this tumour, the *Bacillus Calmette-Guérin* infected mice lived significantly longer and frequently showed advanced-to-complete regressive changes in their tumours prior to death. This retardation in *Ca 755* growth and increased survival time has also been observed in mice of a C57 inbred line following *Bacillus Calmette-Guérin* infection.

The beneficial effect of *Bacillus Calmette-Guérin* infection on the outcome of S-180 growth appears most likely to be an expression of a more vigorous or accelerated homograft reaction. Most important, perhaps, is the finding that the mice are still resistant to the growth of S-180 sixty-seven days following infection. The significant degree of protection to *Ca 755* in terms of tumour retardation and prolonged survival time also points to a more competent immune response in the infected host. The increased survival time in infected animals with Ehrlich ascites may reflect an enhanced, though insufficient, antibody response to the inoculated cells; however the results obtained may also be ascribed to a more efficient reaction to endogenous infection which frequently appears to be a contributing factor in the death of tumour bearers.

The studies reported herein have been exclusively concerned with transplanted tumours. Present experiments are in progress to extend these observations to the behaviour of first and second transplant generations of spontaneous tumours in *Bacillus Calmette-Guérin* infected isologous hosts. If some resistance based on an immunological response exists to the development and progression of spontaneous neoplasms, the *Bacillus Calmette-Guérin* infected host with its greatly enhanced capacity to respond to antigenic stimulation deserves special attention in studies concerning tumour immunity.

MICROBIOLOGY

Lowered Bactericidal Efficiency of Hydrogen Peroxide on Milk from Cows treated with Penicillin

DURING the course of experiments on the introduction of hydrogen peroxide as a routine means of raw milk preservation, the following anomaly was observed.

In a certain number of trials, the usual rate of bactericidal efficiency, which normally fluctuated between 80 and 94 per cent of chemically pure 30 per cent hydrogen peroxide used at a concentration of 0.2 per cent was considerably lowered, at times by 30–70 per cent. In certain extreme cases, after one hour of hydrogen peroxide treatment, an actual rise in the initial number of milk microflora population occurred. At the same time many raw milk samples with a high catalase content were examined, where the percentage of destruction by hydrogen peroxide was lowered to 75 per cent of normal compared. It was therefore concluded that the anomalous results were caused by an unknown substance, present in raw milk.

The period of the investigation coincided with the summer of mass antibiotic treatment of the cattle, so we investigated the possibility that antibiotics in the milk were the cause of the interference phenomenon. Large number of milk samples containing penicillin were treated with hydrogen peroxide. The results were consistent with the supposition that the interfering substance was penicillin, which had been secreted into the milk during and after the treatment of the cows. Total counts of milk by the pour plate method were made on Difco tryptone glucose yeast agar, and the observed results revealed significant differences in the percentage of destruction, as compared with those of normal raw milk.

Mixtures of 0.1, 0.5, 1.0, 5.0, 10, 20, 100 µl/ml penicillin (crystalline sodium G) with 0.2 per cent of 30 per cent hydrogen peroxide in distilled water, and raw milk did not decompose hydrogen peroxide directly,

as it could be quantitatively recovered when titrated iodometrically with 0.1 N sodium thiosulphate

It was reasonable to assume that this was not a simple case of chemical interference between the two drugs but a more complex interaction connected with the bacterial cell itself

When added artificially to normal raw milk, the different concentrations of penicillin G in certain cases reproduced the interference while in certain other trials the results were not satisfactory

The experiments were carried out with different kinds of raw milk, ranging in total initial count from 10^3 to 10^8 bacteria/ml and with penicillin concentrations 1.0 0.75, 0.50, 0.25 0.10 0.05 r.u./ml. When the milk microflora had been in contact for two hours with the penicillin and the milk was then treated with 0.2 per cent of 30 per cent hydrogen peroxide the interference was directly proportional to the concentration of penicillin

The unsuccessful results suggest that the phenomenon depends chiefly, not on the quantity, but on the quality of the very unhomogeneous milk microflora. Therefore the behaviour of the various isolated groups of milk microflora, such as lactic organisms, coliforms, psychrophilic organisms, thermotolerant and the thermophilic organisms is now being investigated. Results obtained so far indicate that the thermotolerant organisms may be responsible. The phenomenon described above was also reproducible when the microorganisms were grown and treated in nutrient broth. Further metabolic studies are in progress

Sex Chromatin ('Chromosome') in the Purkinje Nerve Cells of some Mammals

The greater percentage of sex chromatin in the nuclei of somatic cells has been used for determining the genetic tissues of most mammals, excepting the Rodentia and Lagomorpha, the nuclei of which harbour chromatin masses which were wrongly interpreted as sex chromatin. Nevertheless the studies of Luers¹ on the blood cells of Lagomorpha, and of Castro *et al.*² on the ameloblasts of Rodentia showed the possibility of determining the sex in these animals

Most authors state that the detection of the genetic sex is based upon the finding of a single sex chromatin of chromosome³, which is supposed to be present in 70-80 per cent of female nuclei, and 5-30 per cent of male

Nevertheless, we hope to demonstrate that the Purkinje cells provide evidence against the general applicability of such a viewpoint. For, in some animals we encountered a greater percentage of two chromosomes in the female and a single one in the male

Cerebellum tissue from 5 pairs of each of the following species was studied: dog, cat, rabbit and human

Fragments were fixed (12-24 hr.) in 10 per cent formalin buffered to pH 6.9. Frozen sections 20 μ thick were treated by the Foulgen technique and mounted in balsam after diaphanization with creosote. Only intact nuclei in the centre of the section were selected for counting

As can be seen from Table 1 in so far as the dog and cat are concerned we fully agree with other authors. In fact, we found many nuclei with a single chromosome in the female and only a small percentage in the male (in the female, 70 per cent for the dog and 76 per cent for the cat; in the male, 28 per cent for the dog and 30 per cent for the cat)

On the other hand, with regard to humans and the rabbit, as we have already remarked in a previous paper⁴ a higher percentage with two chromosomes in the nuclei was discovered in the female, whereas many nuclei from the male had a single chromosome

Thus, using by the method of Barr and Bertram⁵, is valid only within certain limits. In the case of the Purkinje cells, which we varied between the different groups of mammals selected for study, the diagnosis of sex is possible in both humans and rabbits, when the nuclei containing one or two chromosomes are considered

For the dog and cat, we can apply the principles of Barr and Bertram⁵ that the finding of a higher percentage of cells with a single chromosome points to the female sex. For practical purposes a large number of cells containing one chromosome indicate a female, whereas those with no chromosome indicate a male

Similarly in the case of the humans and rabbits, sections which show a high percentage of cells with a single chromosome indicate a male and those with a greater number of nuclei with two chromosomes indicate a female

It is our impression that these changes in the number and behaviour of the chromosomes can be ascribed either to fusion of the heterochromatins of the sex chromosomes⁶, or to a non specific fusion of heterochromatins of homologous parts of other chromosomes⁴

According to our work in progress, such chromatin masses may confirm what Pavan and Breuer⁷, in *Rhynchocystis angelae* called 'genie secretion', which in mammals would be a manifestation of the so-called 'metabolic chromatin'

GENETICS

Effect of Different Wild-Type Isoalleles on Crossing-over in *Drosophila melanogaster*

EARLY experiments¹ had shown that wild-type stocks of *Drosophila melanogaster* carry different wild-type alleles at the sex-linked, white-eye (*w*) locus. A more recent² detailed genetic analysis demonstrated that the *w*⁺ loci of the Canton-*S* (*C*) and Oregon-*R* (*O*) wild-type stocks differ in the right-hand two of the four recombinationally separate *w*⁺ loci. Thus *C* and *O* may be described by the notation *CC* and *OO*, where each letter represents two of the four loci. Derived wild-types carrying the right and left halves of the two stocks, that is *CO* and *OC*, have been successfully synthesized.¹

Experiments were designed as follows to determine whether the wild-type isoalleles could differentially influence the frequency of crossing-over in their vicinity. Three marker genes, yellow body (*y*), white-cherry eye (*w*^h) and split bristles (*spl*) were selected and crossing-over studied among the progeny of females heterozygous for the three marker genes and either an intact or derived wild-type *X* chromosome. Since the cross-over frequencies for the two intervals are rather low, the standard distances for each being 1.5, the females were also made heterozygous for the autosomal inversions *Cy* and *Ubx*¹³⁰, thereby maximizing the cross-over frequencies. Such a procedure, it was thought, might magnify any differences in crossing-over between the two wild-types should they exist. Paired, parallel experiments were carried out in order to minimize environmental effects on crossing over. For example, crosses were made so that females heterozygous for *CC* and *OO* developed concurrently on the same lot of culture media. Virgin females of each genotype were collected during the same eight-hour interval and three females were collectively mated to *y w spl sn*³ males in half-pint bottles. Three such matings were made with each heterozygote. After three days females were transferred to fresh media for an additional three-day egg-laying period followed by a third three-day period. Culture media from the same lot was used for each egg-laying period, and flies were raised in a room whose temperature fluctuated between 22 and 24° C.

Table 1 CROSSING OVER IN FEMALES OF GENOTYPE *y wch spl/wt Cy/±, Ubx*¹³⁰/±

| Source of <i>w</i> ⁺ chromosome | Cross-over frequency and per centage for interval | |
|--|---|-----------------|
| | <i>y wch</i> | <i>wch spl</i> |
| <i>CC</i> | 285/8526 (3.58) | 114/8525 (1.74) |
| <i>OO</i> | 240/5210 (4.60) | 125/5210 (2.39) |
| <i>OC</i> | 104/2705 (3.84) | 48/2705 (1.77) |
| <i>CO</i> | 180/4037 (4.40) | 82/4037 (2.03) |
| <i>CrCr</i> | 332/4375 (7.59) | 90/4375 (2.06) |
| <i>FF</i> | 451/5787 (7.79) | 187/5787 (3.07) |
| <i>FCr</i> | 232/6458 (3.59) | 92/6458 (1.42) |
| <i>CrF</i> | 232/4458 (5.17) | 92/4458 (2.05) |

In Table 1 results of the crossing-over experiments have been compiled. The frequencies listed represent summations of all the progeny scored for each cross. It will be noted that the cross-over frequencies for each interval are greater among females heterozygous for *OO* than for *CC*. That this difference is apparently a

function of the right segment of the *w*⁺ region is borne out by comparable crosses where the derived wild-type chromosomes *CO* and *OC* were employed. These results, included in Table 1, show that for each interval the cross-over frequency was greater among females heterozygous for *CO* than for those heterozygous for *OC*. A comparison between the total cross over frequencies for all females whose right *w*⁺ segment was *O* with that of females whose right *w*⁺ segment was *C* established this difference to be statistically significant ($\chi^2 = 9.04$, 1 d.f., $P < 0.01$).

That the aforementioned differences in cross-over frequencies are not spurious is supported by a completely independent set of crosses. Crossing-over experiments were repeated employing intact and derived wild-type *X* chromosomes coming from two wild-type stocks of independent origin, Formosa (*F*) and Crimea (*Cr*). Genetic analysis of these stocks³ established that *F* and *Cr* carry different wild-type isoalleles in the right segments of their *w*⁺ loci. Insofar as can be determined at present these wild-type isoalleles of *F* and *C* are identical as are those of *Cr* and *O*. Parallel experiments were carried out. In one crossing-over in females heterozygous for *FF* or *CrCr* wild-type *X* chromosomes was compared, in the second females were heterozygous for *CrF* or *FCr*. Inversions were included as noted above.

The results of these experiments, listed in Table 1, parallel precisely those obtained with *O* and *C*. Thus for each interval the cross over frequency was greater in females whose right-half *w*⁺ loci carried the *F* isoalleles as compared with those carrying the *Cr* isoalleles. Compared statistically the difference between the total cross-over frequency for all females whose right segment was *Cr* and those whose right segment was *F* is highly significant ($\chi^2 = 34.8$, 1 d.f., $P < 0.001$). These data demonstrate that the presence of a particular wild type isoallele can influence significantly the cross over frequency in its immediate vicinity.

That the differences in cross-over frequency are a primary function of the distinctive wild-type isoalleles is supported by a number of facts. A significant maternal effect seems unlikely since identical females were used throughout in obtaining heterozygotes. Specific autosomal influences are of doubtful importance, especially since the autosomes were randomized while synthesizing the derived wild-types. Interaction effects are, however, not excluded. Precisely how the different isoalleles effect cross-over differences is not clear. One possibility is that they have different pairing affinities for the mutated allele to which they were tested.

These observations serve to explain, in part, the recombination differences between the Oregon and Samarkand wild-types of *D. melanogaster* reported by Lawrence.⁴ They also point to the fact that wild type isoalleles may have important evolutionary significance by providing a base from which genotype producing high or low crossing-over frequencies can be selected.

THE DISCIPLINE OF THE SCIENTIFIC METHOD

THE address, "The Message of Science", which Prof P Weiss delivered at the Universal and International Exposition at Brussels on June 25 1958 and which has now been issued as an Occasional Paper of the Rockefeller Institute, develops three main points. Man's hope lies in the advance of civilization, of which science is a part, and to understand the role of science requires insight into its nature, power and limitations. First Prof Weiss argues, man will continue to reap rich fruit from scientific progress. Secondly, understanding the process of science gives man a firmer grounding in reality against his floundering and fumbling in abstractions and thirdly the task of science is to serve man by mastering Nature and not to become man's master. In serving man, science, Prof Weiss urges, must close ranks with other servants of humanity—the creative arts, philosophy, religion—all striving for a new integrated humanism.

In this view, science which has helped to dethrone man from his self appropriated station as the centre of the universe, can help him now to grow into his rightful stature. Prof Weiss's address is thus essentially a contribution to the discussion on the place of the universities in the scientific revolution which Sir Eric Ashby opened in "Technology and the Academics" and which Sir Charles Snow has developed further in his Rede Lecture, "The Two Cultures and the Scientific Revolution".* Prof Weiss does not disparage the material benefits which science can provide, but he lays his stress on the contribution which science can offer to man's intellectual and moral advance. It would be a distortion to suggest that he is advocating science for its own sake but, like Sir Edward Appleton in his presidential address in 1953 to the British Association, he maintains that science itself is one of the great human values.

The power of science Dr Weiss points out, comes from the strict mental discipline and critical detachment that it imparts to those who live and practise by its code, and if living by this code can help men to lead more satisfying lives, so as more fully to enjoy and share promised release from want and drudgery, if science will not just extend man's span of life but also give the content of that span more purpose, if science can convince man that many of the evils and errors and convulsions of the present age arise from his ignorance and neglect of the very code of science then science will have given him another noble gift, namely, a basis for responsible and judicious self-direction as a design for living. This presupposes that man is free to choose his course for better or for

worse, and in this choice, the scientific approach can help him to avoid predictably disastrous turns and missteps. Science is not to blame for man's misdirecting scientific knowledge to evil ends.

If the scientific spirit can teach man reason, the message of science must, however, first be accepted by man and it is Sir Charles Snow's contention that one of the two cultures he predicates as existing does not and will not accept that message. First, however the characteristics which Dr Weiss describes as marking the scientific spirit as superior to the mere application of logic, the Golden Rule or just plain common sense should be noted. It is the categorical demand for validation and verification of each premise each contention and each conclusion by the most rigorous and critical tests of evidence. Every rule and law have to be tested and enforced, and nowhere else is the penalty for error or infringement so prompt and telling.

This discipline of the scientific method broadly applied, could go far toward clearing the underbrush of superstition and prejudice that hampers civilization in its march, but it has its limitations. Since according to the code of science, no positive assertions are final and all propositions approximations and indeed provisional, science is seen to advance more by denying what is wrong than by asserting what is right—by reducing and eventually eradicating errors rather than by bounding straight toward some preconceived final truth. From any point along the frontier of knowledge which mankind faces the imagination and curiosity of individuals may start tracks that radiate in all directions into the unknown. Through trial and error the right path is gradually singled out from the multitude of blind alleys by the fact that it has met, instead of missing other new or familiar lines starting from other points, merging with them in mutual reinforcement. Success lies in the confluence of thoughts from many diverse directions, and this gives science its coherence and consistency with a stable inter-convertible currency of terms and units, modes of operation and standards of proof or disproof, all gained by gradually removing the inconsistencies and incongruities within the system, by the systematic reduction of margins for error.

Dr Weiss points out that this is the method of organic evolution, but on the infinitely faster scale of thought processes, which require much less time to establish their soundness; and from this comes man's unprecedented chance for rapid progress—from the incessant wading out of error. Moreover, for science as a whole, truth is that strip of possibilities left over after all demonstrable untruths have been eliminated, there will remain a fairly

* "The Two Cultures and the Scientific Revolution," by Sir Charles Snow (The Rede Lecture 1959) Pp iv + 322. (Cambridge: At the University Press 1959) 5s 6d net.

broad band of uncertainty, including the indeterminate, the unknown, the indeterminable and the unknowable. The limits of science are frankly acknowledged, and Dr Weiss has no place for either the shallow optimism that Sir Charles Snow marked as contributing to the divergence of the two cultures he describes, or for the uncritical claim that science is a cure for all the ills of mankind and that it can prescribe ultimate goals to guide man's conduct. On the contrary, the humility and courage required to live with partial answers and the disturbance of complacency should assist science—and the scientist—to live with the other claimants to a share in human destiny. The scientific spirit, by stimulating man afresh to search and strive again rather than to conform, to face problems and not to accept past solutions, and to exercise ingenuity instead of abdicating to authority, could rekindle flames which mechanization threatens to extinguish.

Dr Weiss's view of the relations of science with the creative arts, with philosophy, with at least the kernel of religions (not of creeds) and with the lessons taught by history, all of which are companions with science in shaping the fate of mankind, presupposes, however, a bridge rather than the gulf which leads Sir Charles Snow to speak of the two cultures—it invokes comprehension rather than incomprehension on both sides. If the attitude which he depicts should prevent the scientist from contributing to misunderstanding or stirring up resentment, there must none the less be understanding and not prejudice on the other side. It will not suffice for science to be objective, to recognize soberly its own limits, and to claim no greater share of man's allegiance than it can ask on scientific grounds. It can scarcely act as educator unless there is sympathy and receptiveness on the other side. That must precede the abatement of suspicion and resentment, the removal of barriers due to prejudice and the disappearance of any fears of aggressive expansionism of science.

This exposition of the message of science ends with an appeal that men of science should close the ranks with those in other walks of life against the dehumanization of our culture, and that they should look and work for a broad humanism in which science is accepted, not grudgingly but with understanding, by all men in all walks of life, not for its fruits alone but for the ideal of rational thought which it can carry to its highest culmination. At the same time, men of science must ever be on their guard against the danger of specialist isolation to the neglect of other human values, and finally Dr Weiss pleads that science should re-acclaim diversity as the source of progress, including the diversity of human minds in their responsible expression. Simultaneously, he pleads that those humanists who are not scientists should not regard themselves as the prime custodians of civilization, shunning science as if it were inhuman.

The conception of the message of science and the place of the scientist in our civilization which Dr Weiss expounds in this address is dignified and noble as well as restrained, it could well elicit the response he seeks from the non-scientists if it can reach them.

But while Dr. Weiss recognizes as clearly as Sir Charles Snow the gap between the two cultures and the imperative need for co-operation between scientist and non-scientist, he does not indicate how the gap is to be bridged. It is true that, if his counsel is followed, scientists could do a good deal to remove the prejudices and suspicions which have enlarged the gap—or at least to remove the substance of those prejudices and suspicions, but something more is required to restore unity to the intellectual life of Western society, or even to provide a meeting place for the two cultures. The lack of comprehension of science and technology on the part of the non-scientist which leads Sir Charles Snow to describe the literary intellectuals as natural Luddites must be removed also, and this as he sees clearly is a problem of education. Until intellectuals and the nation generally come to understand the scientific revolution and its implications, Britain cannot hope to cope with the problems offered and either avert the dangers or exploit their possibilities.

Sir Charles Snow faces this question in the last part of his lecture. He believes that we need as many outstanding scientists as the country can produce. They present no problem, but their number is limited, and they need a much larger number of professional scientists for the supporting research and high-class design and development, here the problem is not so much that of quality as numbers. These in turn require a large number of supporting technologists and technicians for the secondary technical jobs, some of whom will take major responsibility, particularly in the human jobs. Here our problem is both the numbers required, which will throw an immense strain on the universities, university colleges, colleges of technology and technical colleges of Britain, and the distribution of ability in order that proper and efficient use may be made of their services. Lastly, there must be not merely politicians and administrators, but also an entire community knowing enough science to have a sense of what the scientists are doing.

Sir Charles offers no prescription as to how all this is to be achieved. He simply presents the challenge to the educational system of the country, with the reminder that our real assets in the world to-day are our wits—our capacity for co-operation and our inventive and creative ability. The survival of Britain as a world power requires that we should fully understand the scientific revolution, educate ourselves to the limit and give the lead to the world. We cannot do this without breaking the existing pattern of education, but unless we do so and educate ourselves adequately, we must experience in our own life-time a steep decline in our standards of living. To close the gap between the two cultures is a necessity in the most abstract intellectual sense, as well as in the most practical, in order that we may be able to achieve even the political techniques which will enable us to bring our human capabilities into action. Once again we are summoned to look at education in the broadest sense, and Dr Weiss's message is an invaluable contribution to such a task.

LATIN IN UNIVERSITY ENTRANCE REQUIREMENTS

THE controversy about compulsory Latin for entrance to Oxford and Cambridge flares up sporadically, like the plague, but it does look as though the recent outbreak may be the last. True, Oxford has reversed its decision to make German and Russian alternatives to Latin, but when the committee at present looking into the qualifications for university entrance reports, it seems likely that some means will be recommended whereby Latin can be avoided.

It is difficult to see what benefit the average boy (or girl) who wants to specialize in science can derive from Latin at Ordinary level in the General Certificate of Education. He will not be able to read the simplest texts with any ease, even if he wanted to and the feeling among many scientists that Latin is a waste of time makes it very unlikely that he will. His attitude to Latin which is often crammed in a few months and as quickly forgotten, is one of resigned hostility.

Without Latin the specialists will become even more specialized: is a favourite argument of the anti-abolitionists, yet very few people wish to abolish it unconditionally. At Oxford the suggestion was that Russian and German should be alternatives and a scientist with French and German is no more a specialist than one with French and Latin. Besides, there is far more chance that a modern language will be kept up, since even the least materialistically minded can see its usefulness. More and more people go abroad every year especially school children and university students, and later on the professional scientist will want to read papers in foreign languages. Few are published in Latin.

Three main arguments are advanced by those who wish to see Latin retained besides the one mentioned above.

First, they say that it is the key to the understanding of Western culture. Quite apart from the fact that Latin at Ordinary level is not even a key to the understanding of Latin in order to understand Western culture one has to know a good deal about it, and as is so frequently pointed out most scientists do not—though many are more knowledgeable than is often allowed. Latin is no doubt, an immense asset to the scholar with a wide knowledge of the literature, philosophy, art and history of Europe and America but to the scientist it is rather like studying the quantum theory without knowing what radiation and algebra are, or to take a non-scientific simile to study the sources of Shakespeare's plays without having read "Hamlet". With an educational system which imposes specialization at the age of fifteen we cannot afford the time for intellectual luxuries. It is the stuff of Western culture that should be studied not Latin grammar.

Secondly Latin is said to be a unique training for the mind. This argument is difficult to refute since it is so vague and is so seldom elaborated. It is significant that it is usually advanced by people

whose mental training was largely based on Latin. Furthermore, mathematicians can make a similar claim for mathematics with equal justice. Part of the uniqueness of Latin is said to lie in its being a highly inflected and so a very precise, language but so are German and Russian.

Thirdly, Latin is said to improve one's English. Maybe it does, but it is an extraordinarily round about way of doing so, and one for which the scientist simply does not have the time.

In fact, Latin tends to defeat the very objects it is meant to attain. It becomes associated with other non-scientific subjects and produces an anti-cultural reflex—Latin is a waste of time therefore French history and English are a waste of time. It also takes up valuable hours in school which might be devoted to arts subjects likely to interest the potential scientist. It is not suggested that the time spent on Latin should be given over to more science. A debate held recently in the University of London on the motion "That the Education of our Future Rulers should be primarily in the Sciences rather than the Humanities" where scarcely a speaker from an audience containing many scientists supported the motion, shows how much basic agreement there is that education ought not to become too specialized. In view of this, it is a pity that such an issue should have been made out of the relatively unimportant Latin question.

It is high time that some effort was made towards improving the general as opposed to the specialized standards for university entrance. If the Latin dispute does nothing else, it focuses attention on this need. Scientists entering for State scholarships already have to take a general paper in English, but it is a special paper for scientists and so in a sense it condones the existence of Sir Charles Snow's two cultures, instead of tending to reunite them. If only the universities would demand from everyone three subjects at Advanced level, one a science and one an arts subject, there would be no need to quibble about trivialities like Ordinary level Latin. Quite apart from the wider knowledge this would bring scientists and arts men would be working together right up to the time they left school, and this is surely essential if they are not to separate into two groups. It has been suggested that as a consequence there would be a slight lowering of standards in the entrance scholarships, and that the colleges would not accept this. If so, it would be a great pity, but it would be a very small price to pay. Besides it is illogical to complain about specialization and to object to measures which combat it.

Anyone who wants to see compulsory Latin retained for scientists should sit back and ask himself two questions. What am I trying to achieve? What is the best way of going about it? It is very peculiar reasoning that produces Latin at Ordinary level as an essential part of the final answer. The worthy cause of a wider education is being discredited.

THE LIFE OF FREDERICK SODDY

Pioneer Research on the Atom

The Life Story of Frederick Soddy By Muriel Howorth Pp 362+16 plates (London New World Publications, 1958) 75s

THIS is an uneven and uneasy book. The scientist who reads it is likely to be exasperated by its not infrequent confusions and repetitions—and the general reader will almost certainly find its detailed chronology difficult if not impossible to disentangle, although the framework of the story is simple enough. It is the life-story of Frederick Soddy, pieced together from his casual remarks, from reluctant replies to leading questions, from more sustained and possibly more spontaneous reminiscence, and from the residue of his papers, by his literary executrix and friend of his later years. It is a work of obvious devotion, forcefully and at times movingly written, but it achieves no real synthesis.

Readers of this journal will remember Paneth's tribute to Soddy (*Nature*, 180, 1085, 1957) within the compass of a short article, that was generous, just and discerning, written by an expert in his own field who had known him when he was still active in it. Paneth wrote "The duty to clarify his picture is specially incumbent on us, as it is the tragedy of his life that members of the younger generation may know him only as the person who adopted the term 'isotope', and, perhaps, as the author of provocative statements in economics and other fields far remote from science. The number of those who knew Soddy in his creative period is dwindling. He was gifted in many, perhaps too many, ways. He was such a good writer of English prose that it was all too easy for him to give his polemical essays the sting he wished."

Frederick Soddy died on September 22, 1956, in his eightieth year. His last contribution to the literature of radioactivity was a letter to *Nature* published on September 3, 1932. His present biographer met him first in January 1953. She had then recently read "The Interpretation of Radium" (1909) and had been so impressed by its philosophy that she had sought out its author. At their first meeting she suggested to Soddy that they should "together write the record of his scientific investigations." Within a few days she had his agreement. Within two months the preface, at least, to "Atomic Transmutation: the Greatest Discovery ever Made" had been written. This was to be Volume 1 of the *Memoirs*. Volume 2 was unfinished at Soddy's death. Then Major and Mrs. Howorth came into possession, through Soddy's will, of "all his original papers, letters, and records." In that way the book now under review had its beginning, its conception replacing that of the half-finished *Memoirs*. "Having these [original papers] as my guide", Mrs. Howorth confides in her new preface, "I can now write, with less presumption and more confidence, the story of this remarkable man who was destined to play so great a part in the discovery of one of Nature's phenomena, unique in its potentialities and formidable in its power."

It appears to me necessary to give this brief history of Mrs. Howorth's book—essentially in her own words—but having done so I am left with scant space to comment on it further. In any event I should require many pages to deal with it in detail. I can

only indicate its shortcomings and its virtues by further quotation. "Later, when the speaker at one of the Royal Society Popular Lectures in Canada fell sick, Professor Cox telephoned Rutherford to take his place and this led to his being accorded a Fellowship of the Royal Society of Canada and eventually to the full London Fellowship in 1903" (p. 78), "Superb chemist that she was Marie Curie had foreseen these events, but it was left to Frederick Soddy to establish each one of them by experiment—natural transmutation, 1901, disintegration theory, 1902, displacement law, 1911" (p. 93), "By 1905 it was still not confirmed that the alpha particle was a helium nucleus" (p. 114), "In 1932, Harkins's 'neutron' had been experimentally established by Chadwick. Later Chadwick went to study in Germany under Nernst and Rubens" (p. 129), "when Cockcroft and Walton in the Cavendish Laboratory succeeded in 'splitting the atom' Cockcroft alone received the award [of a Nobel prize]" (p. 188), "What exactly is a beautiful equation?" I asked [Professor Dirac] "Is Einstein's little mass-energy equation beautiful?" "No, that is not beautiful," he replied, "but some equations are very beautiful indeed" (p. 257), "One can say that on Soddy's perception the whole of nuclear science has been built" (p. 267), "The loneliness which such inattention from the scientific world creates is sometimes not easy to bear without resentment. It may be also, in the case of Soddy, that the loneliness of his early days returned. One could imagine that his mother died three times, once in his infancy, once with the death of his wife, and once on his retirement from academic life" (p. 277).

I do not think that the historian of the science of this century will pass over the work and the worth of Frederick Soddy, as he himself found it for a season passed over—or imagined that he found it passed over—in his later years. He is assured of the esteem of posterity, without special pleading. Mrs. Howorth's book contains much that will be of interest to the historian, but her special pleading is likely to pass him by.

NORMAN FEATHER

GUIDE TO MODERN PHYSICS

Handbook of Physics

Edited by Dr E. U. Condon and Dr Hugh Odishaw (McGraw-Hill Handbooks) Pp xxvi+1462 (London McGraw-Hill Publishing Company, Ltd, 1958) 194s

THIS is a magnificent book. It contains about 1,500 pages and weighs nearly 3 kgm, dimensions which are achieved by solid packing of authoritative information, with little padding or wordy introductions. We have considered it from the points of view both of the senior who has had ample opportunity of forgetting his physics, and of the student who is in the process of acquiring it. For both it seems to be an excellent work of reference.

It is divided into nine parts: mathematics, mechanics of rigid bodies, mechanics of deformable bodies, electricity and magnetism, heat and thermodynamics, optics, atomic physics, solid state, and nuclear physics. Each part is divided into about ten chapters, each written by a specialist; there are nearly ninety contributors, practically all from the United States. The list of chapters would be too long

to enumerate here but some idea of the contents can be given by saying that the topics are those in which there is considerable interest at the present time. The book gives a general impression of the rapid development of physics in many different directions.

This development has introduced the usual difficulties in keeping the subject matter up to date, and in the preface the editors express some concern about their success. They need not have worried, most physicists would be only too delighted to keep within hailing distance of the amount of physics in this book.

In fact the main criticism of the book is that it does not seem clear about its own purpose. In the preface the editors imply—but do not clearly state—that they regard the contents as “What every physicist ought to know. Surely the claim is outrageous? There can be very few people who have the mental capacity for absorbing all this material, and it is questionable whether such people would best serve physics by spending the time needed for its absorption.

In our opinion the main purpose of the book is to serve as a work of reference for the expert who has occasion to wander into a field related to his own but unfamiliar to him. He will find the general principles authoritatively and clearly set out and will be able to see the types of mathematical approaches that are used. He will not usually find experimental details—except for occasional chapters on such subjects as experimental stress analysis and vacuum technique—since the book is essentially theoretical.

The mathematical part of the book is perhaps the least satisfactory. It contains some elementary material such as logarithms which seems out of place and some such as the theory of probability which is likely to be of more use to biologists than to physicists. On the other hand the theory of errors is not treated. Nevertheless the main content is extremely good and well set out.

The book is beautifully printed and produced, and we have noted only very few misprints and mistakes. Unfortunately, the very high price—which is quite reasonable for the amount of material contained—will probably rule it out for most individual physicists. It should nevertheless be in every library and more important every physicist should know of its existence.

H. LIPSON
S. G. LIPSON

REACTION KINETICS

Some Problems in Chemical Kinetics and Reactivity Vol. I

By N. N. Semenov. Translated by Michael Boudart. Pp. xii+230 (Princeton, N.J. Princeton University Press. London: Oxford University Press 1958) 36s net.

THIS is the second English translation of the first volume of Prof. Semenov's book on *Some Problems in Chemical Kinetics and Reactivity* to appear in the past few months. Reading it one is immediately struck by the strength of the author's grasp of the fundamental issues of reaction kinetics and by his ability to marshal the evidence in a subject where the experimental results are often confused, and their interpretations conflicting.

The volume under review has no pretensions to being a text-book, and is in fact an extended version of an introduction to a symposium held in Moscow. It thereby retains a certain freshness and is notable for the provocative and stimulating points of view which it takes. It begins with a classification and account of reactions of monoradicals (no nonsense about ‘what is a radical?’), a chapter which is to be commended for its discussions on bond energies and the relation of energy of activation to heat of reaction, and for the cautious but telling way in which the relation of structure to reactivity is dealt with. The next section is on competition between monoradical reactions, and here a clear account of the role of peroxides in oxidation of hydrocarbons is to be found—a great deal of modern Russian work of value much of it unfamiliar to this reviewer is dealt with here. The mechanism of chain decompositions of hydrocarbons is discussed.

In dealing with biradicals a distinction between the physical concept (triplet state paramagnetism) and the chemical concept (absence of activation barriers, tendency to dimerize, weakness of the second bond) is exemplified at the outset although there is a general coincidence. The chemical aspects as would be expected are stressed.

After this survey the second (and final) part of the volume deals with chain initiation and termination. This is divided into chapters on dissociation of molecules and recombination of radicals (essentially by homogeneous processes), initiation by ions of variable valence, and the influence of the walls of the reaction vessel. All these are excellent, the last being particularly recommended. It leads to some interesting speculations on the processes of heterogeneous catalysis.

The standard of production of the book is not high, the typescript being rather unsatisfactory with an irritating and unnecessary symbol for the chlorine atom. The translation is quite good, although marred by a few words like ‘organism’, and expressions such as the ion impact method imagined by V. L. Tal'roze. For a physical chemist however this book of Semenov's should be compulsory reading.

T. M. SUGDEN

CHEMICAL OCEANOGRAPHY

Apparatus and Methods of Oceanography

By Dr H. Barnes. Part I. Chemical. Pp. 341 (London: George Allen and Unwin, Ltd. 1950) 40s net.

THE special methods of analysis used in chemical oceanography and marine biology are to be found in a great many different publications some of which have limited circulations. There is a need for a collection of working methods, preferably with some guidance for the inexperienced. The need is very competently met by this book. Although suitable for the experienced analyst it is also explicitly intended to help biologists with less chemical knowledge, and to be useful to those with small libraries. The author has therefore devoted the first quarter of the book to three chapters on colour comparisons and photometric analysis to errors and precision, and to the calculation of results. It is difficult to judge the value of this part of the book. It is well done—indeed it is admirably clear—but much of it

seems unnecessarily elementary, and some of the instruments described are surely obsolete

The rest of the book is very useful indeed. Separate chapters (several for nitrogen and phosphorus) give methods for determination of chlorinity, pH, nitrogen, phosphorus, silicon, carbon, oxygen, alkalinity (an account of the carbon dioxide system is inter-polated), conservative elements by micro methods, trace metals and plankton pigments. Others describe filtration methods, and sediment analysis. In each chapter, introductory notes explain the application and chemistry of the methods, which are then given tersely in a form easy to follow at the bench. Remarks on matters of technique, interference, and accuracy come last. The methods are well chosen and it is evident that Dr Barnes is drawing on considerable experience. It is a little surprising that he does not mention the determination of pH with indicators, as it is easy to get quite good results with very simple gear. He should be well able to explain and set out the corrections needed for this method, which is still in use.

There are more than 420 references, some 60 of which are in an appendix bringing them up to July 1958. These are invaluable, although there are few from Russian sources. The 45 tables are mostly relevant, but it is not easy to see the need for reciprocals of atomic weights, nor for a complete list of the symbols recommended by the Chemical Society. The index is thorough. The binding and paper seem rather too absorbent for a book which is certain to be used a great deal on the laboratory bench.

F A J ARMSTRONG

ATLANTIC HYDROMEDUSAE

The Carlsberg Foundation's Oceanographical Expedition round the World 1928-30 and Previous "Dana" Expeditions

"Dana" Report No 46. The Hydromedusae of the Atlantic Ocean and Adjacent Waters. By P L Kramp. Pp 283+2 plates (Copenhagen: Andr. Fred. Høst and Son, 1959). 60 Danish kr.

THIS work, by one of the world's most knowledgeable experts on the subject, is a valuable addition to the excellent series of *Dana Reports*. It will partly replace and partly help to guide us to the multitudinous works on medusae in so many scattered journals, although it has not a complete literature list.

One might wonder how far this new volume overlaps Russell's monograph on the "Medusae of the British Isles" published in 1953 and if it is necessary or desirable for both to be at hand. That there is considerable overlap is inevitable and as it should be, but the two serve distinct purposes. Russell is confined to British waters—but not as defined by the Convention!—and it has much more detailed descriptions with details of the hydroids and their development where these are known. Kramp covers a much wider field. An example which illustrates this difference is given by the genus *Phialidium*. Russell describes two species but Kramp twelve and four doubtful ones. Kramp's description of *P. hemisphaericum* is contained in ten lines, and Russell's in ten pages.

This new report is in three sections. The first occupies 74 pages and is a systematic account of the species taken on the *Dana* cruise, 1928-30, and in collections made at the request of the *Dana* Committee. Not

only are very full taxonomic descriptions given, often clearing up doubtful nomenclature, but also brief but useful summaries of distribution, both geographically and in depth. It contains descriptions of three new species and one new subspecies.

The second section, of more than a hundred pages, is a survey of all the hydromedusae which have up to now been found in the Atlantic and adjacent waters, a term interpreted to include the Caribbean, Davis Strait and Baffin Bay, the Mediterranean, Black Sea and the waters north of European USSR. Truly a wonderful coverage. This section will be a boon to those struggling with the systematics of medusae as it has a diagnosis of every family, genus and species, and with keys to all species at present considered valid. It makes extensive use of Russell's book and his Plankton Sheets for those species that are given therein, but its wider field will make it a most valuable aid towards the determination of medusae by workers everywhere. The descriptions are concise and their arrangement helps to make them simple to follow. The keys, too, are clear, and if only the medusae themselves were always as clear their determination would be much easier. It is scarcely the author's fault that medusae are so often damaged that in practice the answer to some of the questions may be just a question mark. Because of the changes during development the section is confined to the adult forms. This is a pity because so often the young stages found in the plankton can be puzzling. I was disappointed to see that Kramp had not done more to link the medusae with their hydroids as there is now a great deal of information on this, but he probably considered it to be outside the particular relevance of the book. Doubtful species are mentioned in case future research should point to their validity. In this section, too, their distribution is concisely mentioned.

The third section is for the ecologist and it describes the composition of the fauna of the hydromedusae within each of the zoogeographical regions of the area—the Black Sea excluded—and based on the distribution of the water masses. The number of regions is generous in its coverage, with details separately given for four ecological groups—neritic, slope, oceanic epipelagic and bathypelagic—each being regionally subdivided. The neritic group is given extensive subdivision, first into eight major regions, for example, Arctic, East Atlantic Boreal, etc., and then into provinces, for example, Atlantic coasts of the British Isles, Channel, North Sea, Baltic, Norway north of Bergen, Iceland. Russell, in 1935, laid stress on the value of certain medusae as 'indicator species', and the detail given in this section of Kramp's book will be invaluable in this respect. It is only to be expected that further research will widen our knowledge of the distribution of many of the medusae, and although it is obvious that Kramp realizes this (for example, at the bottom of p 266), I found some of his statements too dogmatic, and once in error. On page 210 he says that *Ptychogena lactea* is "entirely lacking in the East-Atlantic boreal region". The *Scoia* took this species in the Faroe Channel in June 1958, and indeed Kramp himself confirmed the identification.

Like other *Dana Reports*, the proof-reading and production have been excellent. Those interested in the systematics of medusae or in the ecology of the water masses will certainly want to have this volume, and I have no doubt that their copy will before long be well thumbed.

J H FRASER

An Anthropologist at Work

Writings of Ruth Benedict By Margaret Mead Pp xxii+583+8 plates (London Martin Secker and Warburg Ltd, 1969) 42s

RUTH BENEDICT and Margaret Mead are two of the best-known names in American anthropology, and certainly the best known to the general public because their writings have a popular appeal and have appeared in cheap editions. This is a book by the second about the first, or rather it is a book about Ruth Benedict and her circle among whom Margaret Mead was a prominent figure, as she is in the book. It contains a number of articles—and also poems—by Ruth Benedict interlarded with introductory pages by Margaret Mead. Some of the articles have already appeared in print elsewhere, and the unpublished ones contain so little of scientific interest that it scarcely seems worth while committing them to print, and, indeed it must be said that much of Ruth Benedict's writing fell into the class of higher journalism rather than into that of scientific anthropology. It could, however be said that it is often helpful in evaluating an anthropologist's writings to have some knowledge of him as a person and of his private interests. That would be true, but a brief memoir would have served the purpose better than a book of more than 500 pages and so constructed that the subject of the memoir is constantly interrupted by its editor and the editor by its subject. Moreover even an English anthropologist who might be expected to find an account of his American colleagues of interest, may find as I have the company somewhat dull. Those who are not anthropologists will, I fear, find it tedious for what can be more tedious than the doings and views of persons we have scarcely heard of, and persons of no very great importance? An answer to that question might be the revelation of their feuds and personal antipathies. Some of the gossip may be true and might be spoken, but it ought not to have been published in print so soon—for example what is said about the late Prof Radcliffe Brown for it is not as though relations between other persons mentioned are treated with complete candour. It is a pity that the initial sympathy and admiration which many of us have felt towards Ruth Benedict an able woman who left some important writings behind her, and also towards the centre of the circle, Franz Boas should in the course of reading this memorial volume be lost.

C. E. EVANS PRITCHARD

Nuclear Reactors for Power Generation

Edited by E. Oponshaw Taylor Pp vii+144 (London: George Newnes Ltd, 1958) 21s net

THE basis of this book is a short course of lectures given at the Heriot-Watt College, Edinburgh. The first and the final chapters provide a reasonable survey of the application of nuclear power. The first of these chapters deals with the world energy requirement, and the importance of nuclear power to the United Kingdom, the United States, the U.S.S.R., and the remainder of Europe. The final chapter considers the economic application of nuclear power, dealing with the choice of steam cycle, fuel burn up and the importance of a high load factor. In this latter context pumped storage schemes are discussed.

The five intermediate chapters provide a short technical survey aimed at providing engineers concerned with the construction and operation of nuclear

power plants with a background of information. The text is not intended for the designer. The chapter on materials is the exception, however and is more detailed. Certainly the designer would find it a useful survey of the likely reactor materials. The potential reactor operator would probably advocate more space being allowed for safety and instrumentation, to enable the control systems of the current electricity authorities nuclear power stations to be described in detail.

A considerable training programme for technicians and operators will be necessary as the large nuclear power stations begin to be commissioned from 1960 onwards. This book provides a summary of a typical course.

R. VAUX

Disposal of Radioactive Waste

By K. Saddington and W. L. Tompkins Pp x+102+8 plates (London George Newnes, Ltd, 1958) 17s 6d net

THE disposal of radioactive waste material is a problem which had to be faced when the production of radioisotopes commenced on a large scale both in Great Britain and elsewhere. It will of course, become of increasing importance as the atomic energy power programme expands and the use of radioactive material increases in industry and the medical fields.

The authors have provided a book which should do much to enlighten the general reader and at the same time, act as a useful work of reference for those working in the field of atomic energy.

Although it is claimed that the book is designed to assist sanitary engineers, the main emphasis is on the wastes arising at reactor stations and fuel processing establishments. A more detailed account of the problems arising in industry would have been an advantage.

The important biological aspects are described very fully, perhaps too fully, having in mind the class of reader for whom the book is intended. Certain of the other chapters could have been expanded to provide more guidance to those outside the U.K. Atomic Energy Authority.

It is quite impossible in a book of this size to give a comprehensive account of all the problems and their solutions. Nevertheless the authors are to be congratulated on a good attempt to provide a general survey of the disposal of radioactive wastes.

Selections from Modern Abstract Algebra

By Richard V. Andree Pp vii+212 (London Constable and Co. Ltd, 1958) 42s net

A BETTER title for this book might be "An Easy Introduction to some Ideas in Modern Abstract Algebra". It is often said that abstract algebra demands little manipulative technique but a considerable degree of mathematical maturity, the object of this book is to enable the novice to acquire that maturity starting from little more than basic notions about integers and real and complex numbers. The early chapters discuss logical ideas and concepts such as equivalence classes and congruence in detail with plenty of illustrations and exercises chosen over a wide field, explanations are full and generally careful though the reader may be left in doubt as to whether a postulate is or is not the same thing as an axiom (p. 11) and the description of a series as "convergent perhaps finite" (p. 24) is unfortunate.

Boolean algebra receives adequate discussion with examples from logical puzzles and circuit theory.

Groups, matrices, determinants, fields, rings and ideals are then brought in at a gentle pace, with a wealth of concrete illustration. The author does not disdain to exhibit a diagram of the inter-relations of fields, integral domains, commutative rings, rings, which should help the beginner in the rather tiresome task of remembering the connexions and differences of these concepts. The Cayley-Hamilton theorem for matrices is proved, and in dealing with groups the reader is led to see the importance of the Jordan-Hölder theorem, though the proof is omitted.

The author tells us that the lecture courses on which this book is based have been increasingly popular in the University of Oklahoma, and that engineering students have found the work on Boolean algebra and matrices valuable and stimulating. One can readily believe this, for the style is easy and informal, most readers will be keen to go further, and for them the carefully selected references to more advanced works will be useful. T A A BROADBENT

The Terpenes

By the late Sir John Simonsen and Dr W C J Ross Vol 5 The Triterpenes and their Derivatives—Hydroxy Acids, Hydroxy Lactones, Hydroxyaldehyde Acids, Hydroxyketo Acids and the Stereochemistry of the Triterpenes. With Addenda to Volume 3 by the late Sir John Simonsen and Dr P de Mayo Pp ix+662 (Cambridge At the University Press, 1957) 84s net

VOLUME 5 of this well-known series contains a comprehensive summary, up to about 1954, of work on the subjects named in the title. A few references and rather more ideas date to about 1956. An important section is concerned with the classical stereochemistry of the various then known triterpene skeletons, with some consideration of conformational questions. As in previous volumes, conformational formulae are inadequately used, but the volume marks a distinct improvement in this respect. There is a considerable addendum bringing up to 1956 work on configuration and structure in the sesquiterpene and diterpene series.

Inevitably in a rapidly moving field the book is seriously out of date. For example, a number of structures quoted have been superseded and many others then unknown have since been determined. There is, inevitably, no consideration of important recent methods such as rotational dispersion, but a rather full account of the use of molecular rotation differences. However, it can form a starting point for the research worker and provides some useful summaries of more classical aspects of the subject for teaching purposes. A J BIRCH

Carbon Dioxide in Water, in Wine, in Beer and in other Beverages

By F Justin Miller Pp 49 (Oakland, Calif F Justin Miller, 3166 Birdsall Avenue, 1958) 15 00 dollars

THIS memoir comprises three almost independent essays on (a) a numerical method of representing the gas pressure relationships in various carbonated beverages, (b) the rate at which such beverages become impregnated by the gas, and (c) the rate at which the gas is lost from the carbonated liquids under various conditions. No radically new conceptions are developed but numerous graphical and tabulated data are included and the discussion covers

many vexed questions such as the role of nuclei and agitation in the effervescence of carbonated drinks and the suggestion, not supported in the present thesis, that various forms of bonding of carbon dioxide, for example, to proteins or as "carbonic acid", play a part. Some readers may find the presentation rather verbose and obscure and may feel somewhat perplexed by the description of numerous 'experiments' where it is not always easy to appreciate either the objects or the results. Further more some at least of the ideas will be provocative as, for example, the view that solutions of carbon dioxide in aqueous liquids may be regarded as dispersed systems similar to emulsions. It is further suggested that increasing the level of disturbance during carbonation results in a coarser 'emulsion' so that the gas is entrapped in comparatively large aggregates which are unstable and tend to give rise to over foaming ('wildness' or 'gushing') when the pressure is released. While this view may help in describing the phenomenon of gushing, it leaves out of account much that is known from scientific experiment about this behaviour and moreover does not in any material way contribute towards means of controlling or avoiding the defect. As this is only one example illustrating the general character of this monograph it will be clear that the latter makes no claim to be comprehensive, but, nevertheless, it contains a good deal of interest to the physical chemist as well as much that will be stimulating to the more technical reader. A H COOK

Animal Behaviour

By Dr John Paul Scott (The College Library of Biological Sciences) Pp xi+281+16 plates (Chicago, Ill University of Chicago Press, London Cambridge University Press, 1958) 37s 6d net

THE particular value of this book is that it is comprehensible to reasonably intelligent people who have not steeped themselves in the jargon of the ethologists. It may be used as a text-book because it covers well the general field of animal behaviour, especially in basic social aspects, but the book is also an introduction which will subtly draw the student forward into a wider range of reading. The scientific discipline throughout is commendable.

Animal behaviour is concerned with the activity of the whole organism and groups of organisms: what an animal is doing is as important as what it is, and behaviour is one of the central problems of existence. Dr Scott develops his work from the elements of behaviour, the limitations imposed by anatomy, and the internal causations from physiology, to the subject of learning and the effects of experience. This is straightforward going with field and laboratory illustration, but when the study of organization of behaviour and social organization is reached Dr Scott becomes an inspiring teacher. He is not to be classed with those practitioners in ethology who cannot see wood for trees: he becomes a naturalist seeing individuals and populations in their larger environmental setting. The problems of developing sociality and social disorganization in relation to ecological factors are well chosen and illustrated and the reader is left wondering—a valuable mental state—about the puzzling field of the gene complex in relation to homeostasis and habitat selection in very slightly different races of animals. It is something of an achievement to write so simply without writing down. F FRASER DARLING

THE TANDEM GENERATORS OF THE UNITED KINGDOM ATOMIC ENERGY AUTHORITY

By K W ALLEN and F A JULIAN
Atomic Weapons Research Establishment Aldermaston

W D ALLEN and A E PYRAH
Atomic Energy Research Establishment Harwell

AND

J BLEARS

Metropolitan-Vickers Electrical Co Ltd., Trafford Park, Manchester

THE electrostatic generator, associated with the name of Robert J Van do Graaff, has emerged during recent years as one of the principal instruments in nuclear physics in the range 1-6 MeV. Its advantages are those of flexibility and precision. The type of ion accelerated (proton, deuteron, helium 3, etc.) and its energy can be readily varied while at a given setting the beam energy can be controlled to 0.02 per cent. The principal limitation of the machine is that terminal voltages greater than 6 MV are difficult to attain and until very recently, no electrostatic generator had produced hydrogen ions with energies in excess of 10 MeV. As a result, studies of nuclei using electrostatic generators have been limited to the lighter and medium weight elements. With energies of 12-14 MeV, these studies can be extended to the heaviest elements.

The idea of utilizing the principle of charge-changing to obtain doubling of energy in an accelerator is due to W H Bennett, who patented the idea about twenty two years ago. Renewed interest was shown in the proposal following an article written in 1951 by Alvarez¹, who pointed out many of the advantages associated with voltage-doubling and an important contribution was made by Weismann and Cameron², who developed an ion source which yielded 25 μ amp of negative hydrogen ions.

Briefly, the tandem generator^{3,4} depends on the voltage multiplication which can be achieved by injecting negative ions into an electrostatic generator in which the stack, instead of being single-ended as in a conventional machine, extends throughout the length of the pressure vessel. The negative ion source is thus at earth potential and outside the pressure vessel, a factor which is of importance as we shall see below. Negative ions are conveniently formed by the passage of positive ions through gases at velocities corresponding approximately to the velocities of the outer orbital electrons. These conditions favour the formation

of negative ions at energies of 10 keV. For example a hydrogen ion beam passing through hydrogen gas can emerge with 2 per cent in the form of H⁻. Unwanted particles such as neutrons and electrons, are removed from the negative ion beam by the action of a weak magnetic field before injection into the electrostatic generator. The beam is then

Fig. 1 Model of the tandem generator building at the Atomic Energy Research Establishment Harwell

accelerated by the positive voltage on the central electrode, and as a result of this acceleration, the ions are moving with a centre of mass velocity large compared with that of the outer electrons about the nucleus. In these circumstances, the passage of the ion beam through a thin foil or tube containing gas at low pressure causes electrons to be stripped off, so that the emergent beam consists of positively charged particles. The energy lost by the beam in passing through the stripper is negligible ($<0.5 \text{ keV}$). The positive ions are then further accelerated through the second half of the stack. Thus, an H^- ion of charge e , injected into a stack with a central electrode of V volts, will emerge with energy of $2Ve$ electron volts. Oxygen ions which are injected as O^- and lose, for example, five electrons at the central electrode will finally emerge with an energy $6Ve$, and so on.

The tandem generator has many possibilities. Proton and deuteron beams with energies of $\sim 12 \text{ MeV}$ and oxygen ions with energies of $30\text{--}40 \text{ MeV}$ can readily be obtained. In the more distant future, ion beams of helium, lithium, fluorine and any other element capable of forming negative ions (a criterion which includes about half the periodic table) may be produced. The fact that the ions are generated outside the pressure vessel at or near ground potential means not only that the source of most of the troubles in an electrostatic generator is readily accessible for maintenance, but also that there are virtually no limits to the power consumption, size and complexity of the injector system. Thus, millimicrosecond time of flight techniques, which are important in many experiments, are more readily applied in the tandem generator than in the conventional machines, since deflexion and bunching can be applied to the low-energy beam before injection. Finally, it may be possible in the future to polarize the nuclei of negative ions, and eventually to produce beams of accelerated polarized protons.

A horizontal tandem generator has been developed by the High Voltage Engineering Corporation, of Burlington, Massachusetts, for the Chalk River laboratories of Canada, and came into operation in January of this year, following successful trials in Burlington. In 1956 interest in the tandem generator was growing in the United Kingdom Atomic Energy Authority, because the potentialities of the machine as a tool for nuclear research have a direct bearing on the atomic energy programme. Thus, precision studies of the energy-levels of the heaviest elements can for the first time be made with beams of protons or deuterons from the machine, similar studies can be made of the energy-levels and level densities in the region of the periodic table occupied by the fission products. Finally, the availability of high-energy deuteron beams makes possible neutron

Fig 2 Arrangement of the gas stripper used to convert negative ions into positive ions in the high-voltage terminal

sources in the region of $8\text{--}12 \text{ MeV}$, a region which has hitherto constituted a gap in the energy of neutron sources readily available from conventional machines.

In June 1956, therefore, it was decided to build two machines for the Atomic Energy Authority, one at the Atomic Weapons Research Establishment, Aldermaston, and the other at the Atomic Energy Research Establishment, Harwell. A contract was placed with Metropolitan-Vickers, Ltd., for the engineering components of the British machines, the Atomic Weapons Research Establishment undertook the development of ion sources and strippers, while the provision of accelerating tubes was the responsibility of the Atomic Energy Research Establishment. A vertical design was chosen because there is no experience in Great Britain of the construction of horizontal machines, and it was felt that the engineering difficulties in a vertical machine would be less severe. There are, however, other advantages in a vertical design. In a vertical machine, a much greater weight of equipment can be placed in the centre terminal, so that the possibility presents itself of using the machine as a conventional single-ended machine as well as a tandem. Also, with a vertical machine, the beam can be delivered to any point in a horizontal plane by 90° deflexion in a single rotatable magnet. In Fig 1 is shown a photograph of the model of the tandem generator at Harwell, the target rooms are disposed in a semi-circle, with two shielding walls dividing the area into three

Fig. 3. Vertical section of the tandem generator.

sections. In this way, experimental equipment can be set up in one room while an experiment is in progress in a neighbouring room.

In the Aldermaston machine, stripping of the negative ions in the centre terminal is achieved by passing the beam through a tube 24 in. long and 0.14 in. in diameter containing oxygen gas at low pressure. Precise control of the injected beam is required in order to maintain an accurate focus at the centre of the stripper tube for all centre terminal voltages in the operating range of the machine. The

advantage of the gas stripper is its indestructibility, however, considerable success has been achieved at Harwell in stripping with thin carbon films 4–5 $\mu\text{m}/\text{cm}^2$ thick, and analysed proton beams up to 2 μamp have been focused on targets. The components of either gas stripper or foil stripper are mounted on a flat plate which forms the greater part of one side of the aluminium alloy chamber (Fig. 2) which joins the two accelerating tubes. The type of stripper or any of its components may therefore be changed at will without affecting the overall alignment of the accelerator.

The injector system, which is described elsewhere¹ is based on a Thonemann ion source used in the manner first suggested by Phillips and Tuck.² It is essentially a positive ion source in which electron exchange with neutral atoms takes place in the exit canal. Lens voltages following the canal are reversed as compared with the typical positive ion source so that only negative ions emerging from the canal are accelerated. After magnetic analysis to remove electrons and unwanted ions, the ion beam from the source is further accelerated and focused by electrostatic lenses. It enters the first accelerating tube of the main machine with an energy in the range 40–120 keV, depending on the centre terminal voltage. An optical method, suggested by R. Middleton, of observing the beam in the centre terminal has shown that a focus about 3 mm in diameter can be obtained.

Identical accelerating tubes each 14 ft long are used in the two halves of the machine. The tubes consist of highly polished aluminium electrodes cemented to accurately ground glass rings. As in the Chalk River machine³, the bulk of the gas used in stripping is pumped down the lower accelerating tube. This minimizes the loss of negative ion beam due to charge neutralization in the upper tube.

The engineering of the machine which will be described elsewhere is shown in section in Fig. 3. The pressure vessel is 45 ft long weighs 45 tons, and when fully pressurized contains about 2 tons weight of nitrogen mixed with carbon dioxide or freon. Access to the machine for general servicing is by the manholes at the base from which personnel can be hoisted by a lift with driving mechanism situated outside the pressure vessel near the top.

The accelerators at both Establishments have been operating satisfactorily for several months. Proton and deuteron beams with energies up to 11.5 MeV have been used in experiments, and currents up to 8 μA at somewhat lower energies are also available.

We wish to express our gratitude to our many colleagues in Harwell, Aldermaston and Metropolitan-Vickers who have contributed to the success of these machines. In particular we should like to mention A. J. Marriott, J. R. Henry and F. A. Howe of Aldermaston, R. H. V. Dawson and J. H. Partridge of Harwell and G. W. C. Cogle and J. Roxburgh of Metropolitan-Vickers.

It is also a pleasure to acknowledge the support and encouragement we have received at all times from Sir William Cook and Mr. D. W. Fry, of the Atomic Energy Authority and the Directors of Metropolitan-Vickers.

UNIVERSITY OF MALAYA IN KUALA LUMPUR

By PROF R D PURCHON

Professor of Zoology, University of Malaya at Singapore

WITHIN less than ten years from its foundation (October 8, 1949) the constitution of the University of Malaya has been radically altered by ordinances enacted by the Governments of the Federation of Malaya and of the Colony of Singapore. The chief purpose of these enactments was to create a new Division of the University at Kuala Lumpur in the Federation of Malaya. The new constitution came into effect on January 15, 1959, and the University now comprises three bodies.

The University of Malaya (chancellor, the Right Hon Malcolm MacDonald, vice-chancellor, Dr A. Oppenheim). The main functions of the University of Malaya are the maintenance of co-ordination between the two Divisions, and the conferment of degrees. The authorities are the Court, the Central Council and the Guild of Graduates.

The University of Malaya in Singapore (principal, A. A. Sandosham). The authorities are the Divisional Council and the Divisional Senate. This Division of the University continues to function as before, except for the transfer to the newly created Division at Kuala Lumpur of the Departments of Geology and Engineering and of certain Departments in the Faculty of Arts.

The University of Malaya in Kuala Lumpur (principal, F. Mason). This is similarly administered by a Divisional Council and a Divisional Senate, and is accorded equal status with the establishment in Singapore. This Division comprises Faculties of Arts, Science and Engineering, while the Department of Agriculture will doubtless be accorded the status of a faculty in the space of a few years. The Department of Engineering was transferred as a whole from Singapore a year ago, and is now fully developed in new buildings in the Pantai valley at Kuala Lumpur. The Department of Geology is in the process of moving, only first-year students being taught in Kuala Lumpur during the present session, when the move has been completed, this subject will cease to be taught at Singapore, thus diminishing the diversity of subjects taught in the University of Malaya in Singapore. However disappointing this may be, this rationalization is unavoidable, at least in the early years under the new constitution.

Development of the University site in the Pantai valley at present includes the completed buildings of the Faculty of Engineering, one residential college and an estate of staff houses. Plans are already at an advanced stage for the buildings for the Faculties of Arts and Science and for the Department of Agriculture. Although these buildings will not be completed for a year, students have been enrolled into the 'intermediate year' of the science course and teaching has begun with skeleton staffs in temporary quarters in a local school, the Victoria Institution.

The Asia Foundation has made a most generous offer of help regarding the provision of a nucleus of books for the library at Kuala Lumpur. Consideration is being given by the University authorities to the methods whereby the books and journals in the library at Singapore can be made available to students in Kuala Lumpur, but care must be taken to ensure that the one excellent library is not split into two mediocre ones.

Appointments to the newly created chairs in science subjects are as follows.

Agriculture The creation of a Faculty of Agriculture at the present time has been made possible by the generosity of the Government of New Zealand, which provided £NZ250,000 specially for this purpose under the Colombo Plan Technical Co-operation Scheme. It is therefore a happy circumstance that the first professor of agriculture should himself be a New Zealander. Prof G. M. Davies, who was born in Dunedin, graduated at the University of Otago and Massey Agricultural College and then spent a further year at Canterbury Agricultural College. During the Second World War he served with the Royal New Zealand Air Force, and won the Distinguished Flying Cross in 1942. After the War, Mr Davies worked for three years in New Zealand, first as a farm appraiser with the State Advances Corporation and then as senior lecturer in soils and fertilizers at Massey Agricultural College. In 1948 Mr Davies moved to the United Kingdom, where he remained for ten years as a regional grassland husbandry officer in the National Agricultural Advisory Service.

Botany Prof M. E. D. Poore, the first incumbent of the chair of botany, brings to the newly created Department several years of ecological experience. Graduating from the Botany School at Cambridge, Dr Poore gained his doctorate in 1954. He studied for a time with Braun-Blanquet in the Montpellier School and then joined the Nature Conservancy at Edinburgh, where he initiated a survey of Scottish mountain vegetation, for which he is well known. He then joined Hunting Technical Services as a consultant ecologist and spent some three years in the Middle East. Here, Dr Poore surveyed the soils, vegetational units and agriculture of Cyprus, Jordan and Iraq with the view of outlining potentialities for agricultural development in these countries.

Chemistry The University of Malaya in Kuala Lumpur is fortunate indeed to have been able to attract Prof R. A. Robinson to this important appointment. Prof Robinson graduated at the University of Birmingham, where he was awarded the degree of Ph.D. in 1929, and the degree of D.Sc. in 1936. Dr Robinson held a Commonwealth Fund Fellowship at the University of Pennsylvania and at Yale University, and then held a Sterling Research Fellowship at Yale. Dr Robinson had appointments at University College, Exeter, and at Auckland University College until the Second World War. During most of the war years he held a senior post in a Chemical Warfare Department. In 1948 he was appointed to the chair of chemistry at the University of Malaya (in Singapore) and holds that post until he returns from a period of study-leave abroad to take up his new appointment in Kuala Lumpur. During his years at Singapore, Prof Robinson has served a full tour of duty as dean of science, and has also served for a period as acting vice-chancellor. He will therefore bring to Kuala Lumpur an invaluable store of administrative experience. Prof Robinson is best known for his research in the field of electrochemistry, and is the author of a standard monograph in this subject.

Geography Prof Robert Ho, who has been appointed to the chair of geography in the University of Malaya in Kuala Lumpur, graduated from King's College, London. He was awarded the degree of M.A. in the University of London in 1950. He has studied soil survey at Rothamsted, and soil analysis in the Department of Agriculture at Oxford. He was appointed to the staff of the Department of Geography in the University of Malaya (in Singapore) in 1948 and has been acting head of that Department from 1957 until his present preferment.

Mathematics The University of Malaya in Kuala Lumpur is fortunate in recruiting Prof O J Eliezer to the chair of mathematics. Prof Eliezer is of Ceylonese nationality; he graduated from the Department of Mathematics at Cambridge, was awarded the degree of D.Sc. in the University of London, and has occupied the chair of mathematics at the University of Ceylon since 1949. He is a mathematical physicist who is best known for his fundamental research in the field of quantum

mechanics. Having served for three years as dean of science in the University of Ceylon, Prof Eliezer will have much experience to offer in the development of the new Faculty of Science at Kuala Lumpur.

Zoology Prof J R Hendrickson, who has been appointed to the chair of zoology, was trained at the University of Arizona and at the University of California at Berkeley and joined the staff of the University of Malaya (in Singapore) in 1951. He is a vertebrate zoologist with wide experience and with special interests in herpetology and ecology. His study of the biology of the green sea turtle will doubtless become known as a classic example of objectivity in field research under difficult conditions. His practical experience of the fauna of the Malayan jungle will enable him to endow his Department with an appropriate trend in teaching and research while his fluency in colloquial Malay will make him especially acceptable in this virile and newly emergent country.

CONTINUOUS-FLOW CULTURE OF THE FILAMENTOUS MOULD *PENICILLIUM CHRYSOGENUM* AND THE CONTROL OF ITS MORPHOLOGY

By S J PIRT and D S CALLOW

Microbiological Research Establishment, Ministry of Supply, Porton

IN a recent report¹ we described the application of continuous flow technique² to culture of the mould *Penicillium chrysogenum*, which is used for penicillin production. This technique has now been used by us to elucidate the influence of pH value on the morphology of *P. chrysogenum* in submerged culture. The morphology of the mould is considered to be of importance in the process of penicillin production³. The role of agitation in determining the morphology of the mould has been stressed by Duckworth and Harris⁴ and by Dion, Carilli, Sermonetti and Chain⁵ but so far the influence of pH value on the morphology has remained unknown. The elucidation of the influence of pH value has been made possible by the advent of reliable means for the accurate control of pH value in cultures over long periods.⁶

Aberrant Forms of Fungi in Submerged Culture

One of the problems of continuous flow culture which we encountered was that the mycelia of newer strains of the mould (H¹s 49-133 and H²s 64 1255) selected for high penicillin production grew initially in a filamentous form but after a time in continuous culture the pellet form of growth was obtained. The main morphological differences between the filamentous and the pellet types of mycelium can be seen by reference to Figs 1a and 3. The pellet type of mycelium was undesirable because with its steady state growth, that is, a constant mycelium concentration in continuous culture, could not be maintained and also its rate of penicillin production was much lower than that of the filamentous form.

Cameo, Sermonetti and Chain⁵ showed that, in batch cultures the mycelium develops in the pellet form if the inoculum is below a certain size, but in our experiments the inoculum was sufficiently large to ensure that the mould grew in the filamentous form

until after the maximum dry weight concentration was reached.

We found that pellet formation was linked with the production of swollen, distorted short hyphae which mark an aberrant form. Duckworth and Harris⁴ in their observations on the production of this aberrant form, included a series of references which emphasized that agitation played a part in the process. The production of short swollen hyphae in vigorously agitated cultures of *P. chrysogenum* under penicillin producing conditions was confirmed by Dion *et al.*⁵ who attributed it to mechanical damage caused by the shearing action of stirring.

It does not seem to have been pointed out previously that abnormally short much branched swollen hyphae similar to those found to be characteristic of agitated cultures of *P. chrysogenum* have also been found to occur in unagitated cultures of fungi under some conditions. Foster⁷, in a short review of this aberrant form, gives references to it going as far back as 1857. Pasteur (quoted at length by Foster⁷), Wolmer⁸, Froy⁹ and Sakamura¹⁰ have reported the production of this aberrant form by *Mucor*, *Penicillium* and *Aspergillus* species. The many different conditions for example, lack of oxygen or high acidity, considered necessary for the formation of these abnormal cells have been summarized by Foster⁷.

In this article we describe how to produce in a vigorously agitated culture of *P. chrysogenum* either the normal, long thin hyphae or the short, swollen type and also how to prevent pellet formation in continuous culture. The importance of control of morphology in continuous flow cultures and in aeration is discussed.

Continuous-flow Culture Method

Cultures were grown in a continuous-culture apparatus developed from the type described by

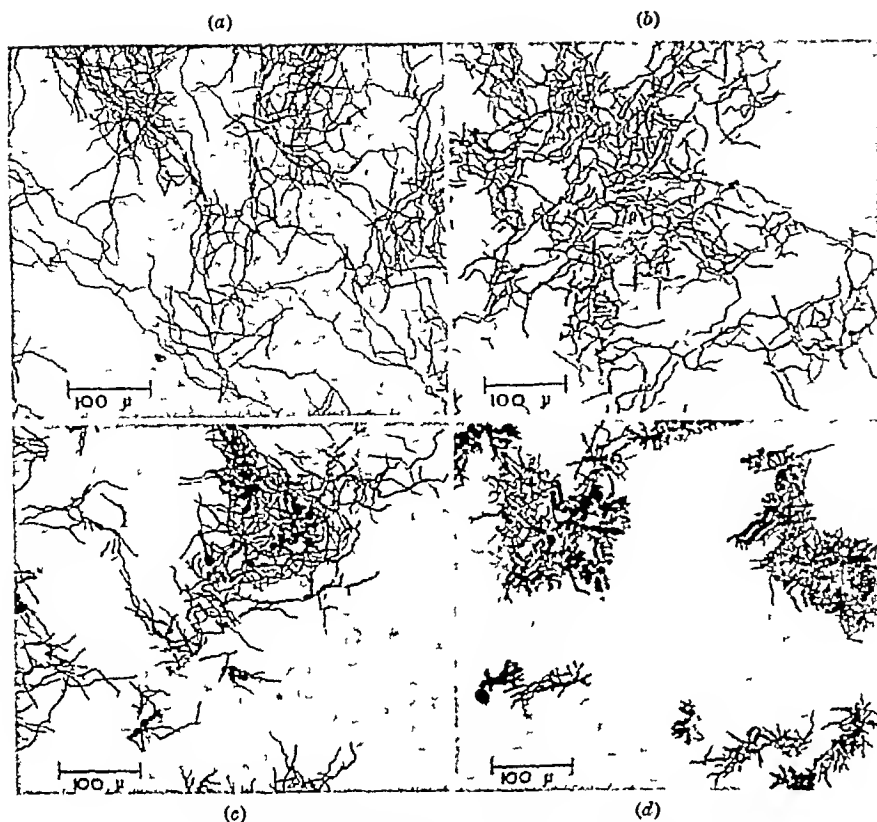

Fig 1 Mycelial forms of strain Wis 54-1255 in cultures grown at different pH values (a) pH 6.0, (b) pH 6.5, (c) pH 6.9, (d) pH 7.4

Elsworth, Meakin, Pirt and Capell¹¹ The pH control system was as described by Callow and Pirt⁵ The composition of the medium was (amounts in gm/l) crystalline magnesium sulphate, 0.25, ferrous sulphate, 0.10, copper sulphate, 0.005, zinc sulphate, 0.02, sodium sulphate, 0.50, manganese sulphate, 0.024, calcium chloride, 0.075, ethylenediamine tetraacetic acid, 0.566, dihydrogen potassium phosphate, 2.0, ammonium sulphate, 6.15, glucose, 20.0, phenylacetic acid, 1.0 The pH value was adjusted with sodium hydroxide In the inoculum culture, which was seeded with spores, phenylacetic acid was excluded from the medium and the glucose concentration was 10 gm/l Growth was limited by the amount of glucose supplied There was an excess of available oxygen Vortex aeration was used with a stirrer speed of 1,200 r.p.m., the impeller diameter was 0.42 times the vessel diameter, the volume of culture in the vessel was 1.7 l An antifoam agent ('Alkatarge-C' (Commercial Solvents, Terre Haute, U.S.A.) 30 per cent (v/v) in liquid paraffin) was added periodically to the cultures at a rate of 0.1 ml every hour The temperature was 25° The dilution rate (flow rate/culture volume) was 0.05 hr⁻¹, so that the average residence time of the mycelium in the culture was 20 hr The duration of culture varied from 200 to 2,000 hr Changes in pH value were made at a rate of 0.1 pH units/hr for the reason given elsewhere¹², and where, also, additional details of the continuous-culture method may be found

The mycelium was stained with cotton blue for the photomicrographs

Morphological Observations

During the initial batchwise growth before flow was started, the mould grew in the filamentous form

until the dry-weight concentration was near the maximum, 0.9 per cent (w/v) Then continuous flow was started and the pH value, which initially was 7.0, was raised to 7.4 in order to bring it near the optimum for penicillin production Under these conditions, for about the first 100 hr, steady state growth was obtained and the dry weight remained at the maximum value The mycelium form was of the aberrant filamentous type described by Dion *et al.*³ The aberrant filamentous form is illustrated in Figs 2b, 4a and 1d The characteristics of the aberrant form were the presence of short, much-branched, swollen and often distorted hyphae For comparison, the normal filamentous type is shown in Fig 1a The normal type is characterized by long, thin hyphae of constant thickness and few branches

After about 100–200 hr in continuous-flow culture at pH 7.4, strains Wis 49–133 and Wis 54–1255 began to form pellets of mycelium and gradually, during a further 100 hr, the aberrant filamentous form gave place almost entirely to the pellet form The initiation

of pellet formation seemed to be agglutination of the hyphae within the individual fragments of mycelium When the mycelium was completely in the pellet form it sedimented like a suspension of sand grains The pellets resembled the sclerotic type described by Thurumalachar and Gopalakrishnan¹³

The strains differed in their ability to form pellets Although all three strains investigated formed the aberrant, filamentous type of mycelium under the conditions stated, strain Wis 47-1564, unlike its descendant strains Wis 49-133 and Wis 54-1255, formed pellets only to a small extent and those that were formed did not persist more than about 100 hr

We discovered, first with strain Wis 47-1564 and confirmed later with strain Wis 54-1255, that pellet formation and the formation of the aberrant and normal filamentous forms were determined by the pH value of the medium The influence of pH value on the morphology of the mould may be seen in Fig 1, which shows the appearance of the mycelium grown at pH values 6.0, 6.5, 6.9 and 7.4 The average length of branches decreased progressively from the order 200 μ at pH 6.0 to 20 μ at pH 7.4 The thickness of hyphae was 2–3 μ at pH 6.0, but at 7.4, owing to the formation of swollen cells, the thickness covered the wider range, 2–18 μ Fig 1d shows the large number of swollen, yeast-like cells produced at pH 7.4 and also the beginning of pellet formation Pellet formation was most marked at pH 7.4 but it did occur to a lesser extent at pH values down to pH 6.7 with strain Wis 54-1255

Lengthening of the hyphae resulted in a marked increase in the viscosity of the culture The culture produced at pH 6.7 and higher values flowed easily like a bacterial culture, whereas the culture grown at pH 6.0 had a porridge-like consistency and flowed with difficulty The dry weights of mycelium in the culture were the same at all pH values

Fig. 2. Normal and aberrant types of mycelium of strain IFis 47-1561: (a) Long thin hyphae (normal type) produced by growth at pH 6.0; (b) short hyphae containing swollen cells (aberrant type) produced by growth at pH 7.4.

The changes in morphology and viscosity accompanying change in pH value were reversed when the pH change was reversed, so that, for example, the pellet or short filamentous form gave place to the long filamentous form when the pH value was lowered and vice versa. Microscope observations showed that the new form of mycelium produced as a result of a pH change arose by new growth from the old form. It was not a transformation of the old form. This was confirmed by the fact that the rate of appearance of the new form was approximately equal to the growth rate after a pH change it took about three days for the old form to disappear almost completely.

The pH value was not the only factor which affected hyphal length and morphology, nutrition also was shown to be a controlling factor. Substitution of the nitrogen source, ammonium sulphate, by corn steep liquor (filtered 4.5 per cent (v/v)) which is a common constituent of the media used in penicillin production increased the hyphal length, reduced the frequency of hyphal branching and prevented the formation of swollen cells at pH 7.4. The effect of addition of corn steep liquor is shown in Fig. 4. These results strongly suggest that corn steep liquor contains some substance which stimulates the production of the normal morphological type.

Fig. 3. Pellet mycelium of strain IFis 40-133 produced at pH 7.4.

Fig. 4. Mycelium of strain IFis 40-133 grown at pH 7.4: (a) With ammonium sulphate as the nitrogen source; (b) with corn steep liquor as nitrogen source.

Conclusions Possible Role of Cell Wall

The conclusions we draw are that during growth of *P. chrysogenum* in agitated culture the hyphal length decreases with increase in the pH value above

6.0, the hyphal length is a minimum at pH 7.0–7.4 and higher values. Extensive formation of swollen cells occurs at pH values above 7.0, this property and the hyphal length being influenced by the medium composition. Pellet formation occurs at pH values above 6.7 but it also shows dependence on strain.

The increase in the length of hyphae with decrease in pH value we interpret to mean that the resistance of the cells to shear increases with decrease in pH value. We attribute the varying resistance to shear and the production of swollen cells to variation in the cell-wall structure. This idea was suggested to us by the recent bacterial studies which have shown that the mechanical strength of a bacterial cell resides in its cell wall, and by analogy we suppose that the resistance of the fungal cell to mechanical forces is determined by its cell-wall structure. This hypothesis implies that the cell-wall structure or composition depends on the pH of the environment during growth. Also swollen cells could be due to a change in cell-wall structure involving loss of rigidity and consequent inability to resist the internal osmotic pressure.

From the practical point of view the long hyphae produced at a low pH value are undesirable because they make the viscosity of the culture high and consequently lower the efficiency of mixing and rate of transfer of oxygen¹⁴. On the other hand, to prevent the extensive formation of pellets and the swollen aberrant form, the pH value during growth should not be greater than 7.0.

Since the optimum pH value for penicillin production is about 7.4 it seems likely that a continuous-

flow process for penicillin production will require two stages, the first stage for growth of the mould with the pH value not exceeding 7.0 and a second stage with a higher pH value for penicillin production¹⁵.

We are grateful to Prof. M. P. Backus of the University of Wisconsin for the gift of strain *Wis* 54-1255. Strains *Wis* 47-1564 and *Wis* 49-133 were obtained from the National Collection of Industrial Bacteria, Department of Scientific and Industrial Research, Teddington. The technical assistance of Mr. J. E. D. Stratton is gratefully acknowledged.

TRANSLOCATION OF COBALT-60 AND CAESIUM-137 BY FUNGI IN AGAR AND SOIL CULTURES

By DR. ERNA GROSSBARD

Grassland Research Institute, Hurley, Berks

AND

DR. D. R. STRANKS

School of Chemistry, University of Leeds

A LONG-TERM research project has been initiated at the Grassland Research Institute on the mechanism of microbial decomposition of grass swards after ploughing back into the soil. These investigations comprise, among others, studies on the manner by which saprophytes progress through the soil from one food-base, that is, an aggregate of plant debris, to another. This will be determined by the phase in which the fungus exists in the soil—whether as dormant spores and resting bodies or as an actively growing, progressive mycelium. In this connection the mechanism of translocation of nutrients by fungi growing in the soil requires elucidation.

Translocation is the movement of nutrients and other materials from one part of the plant to another. As regards higher plants the mechanism of translocation has been studied extensively, but for fungi comparatively little work has been published. Buller¹ investigated protoplasmic streaming in fungi. On the basis of his own work and that of others he concluded that this phenomenon was the principal agent of translocation of nutrients in fungi. Schutte², after studying translocation by means of dyes and

fluorescein, postulated that fungi can be divided into two groups, translocating and non-translocating, and he, too, associated translocation with protoplasmic streaming. The work of Melin and Nilsson^{3,4} and that of Harley and his collaborators^{5,6} on the transfer of nutrients into the host by means of mycorrhiza indicates a translocation mechanism via the mycelium.

Preliminary notes have been published by Grossbard and Stranks⁷⁻⁹ on their attempt to study the growth of soil fungi *in situ* by inoculating soil with a fungal culture labelled with a nuclide emitting gamma-rays. It was hoped that those fungi which produce hyphae in the soil would form a fresh mycelium growing out from the radioactive inoculum. The new hyphae would in turn become radioactive and their distribution could be detected by virtue of the gamma radiations which have the power to penetrate the soil. This technique would depend primarily on the translocation of the nuclide from the radioactive inoculum into the new hyphae, and could provide not only a useful research tool for tracing the growth of fungi in the soil but also help to elucidate the

mechanism of transport of nuclides through the soil via fungal hyphae. This work has been extended and a brief account is given here.

The fungi used in the latest studies were *Pellicularia filamentosa* (Pat.) Rogers (*Rhizoctonia solani*) kindly supplied by Dr S D Garrett, *Helminthosporium sativum* Pemmi, King and Bekko, kindly supplied by Dr J H. Western, *Phycomyces blakesleeanus* Burgeff Herb Imp Mycol Inst 44142, *Phytophthora cactorum* (Leh and Cohn) Schroet Herb Imp Mycol Inst 02471, *Rhizopus stolonifer* (Jehrbach) Lind Herb Imp Mycol Inst 42844.

The nuclides used were cobalt-60 and caesium 137. They were chosen because they emit γ photons in addition to β particles. The fungi were labelled by culturing in media containing the nuclides ($1 \mu\text{Ci/ml}$), which were readily taken up by the mycelium. When grown in broth cultures, 25–50 per cent activity (varying with the conditions of the experiment) could be detected in the total mat after thorough washing.

The main test organisms for the soil cultures were *P. filamentosa* and *R. stolonifer*. Glass tubes filled with sterile soil were used, though occasionally also rectangular boxes. The inoculum for the soil-growth tubes consisted of a number of disks of a radioactive agar culture mixed with soil. This was divided into two halves of approximately equal activity, one of which was killed by heat. Each half was then placed at one end of the soil column in a growth tube. From this inoculum γ rays were emitted which penetrated the soil. Immediately after incorporation of the radioactive mycelium (living or killed) the tubes were scanned with a directional scintillation counter with a collimator (Ekeco model N 559A). This initial measurement served as a standard to check whether migration of the radioisotope via the fungal mycelium occurred after inoculation and to what extent the radioactive inoculum contributed to the counting rate as observed at points away from the initial reference source. The figures in Table 1, columns 1 and 3 referring to *P. filamentosa* cultures show that the highest counting rate outside the wall of the tube was just above the point where the radioactive mycelium had been incorporated. A similar observation was made with *R. stolonifer* and also with *Phytophthora cactorum*. The inoculum of the latter labelled with cobalt-60 was buried several cm deep in soil in a box and the preliminary scan was performed laterally and longitudinally. In soil box cultures of *H. sativum* labelled with caesium 137 the greatest number of counts was also obtained just above the inoculum. This method is useful and can locate with considerable accuracy the position of a radioactive inoculum through soil and the lid and wall of the container.

After inoculation the growth tubes were incubated and counts were made at weekly intervals. Columns 2 and 4 in Table 1 show the counts after 3 weeks. No significant change in counting rate could be observed as compared with the first scan. Also the ratio of activity between 'living' and 'dead' inoculum tube was the same after 3 weeks. However, by that time a fresh mycelium had grown out which could be seen to penetrate the entire soil column. This was particularly evident in the *Pellicularia* culture. However, radioactivity could not be detected in this fresh growth. Similar observations were made with the fungi which were inoculated into soil boxes. The failure to detect any radioactivity in the fresh mycelium by scanning with the scintillation counter may have been due to one of three causes. First the fungi

tested lacked the capacity to translocate cobalt-60 or caesium 137, second the scanning technique with the scintillation counter was inadequate and third, the dilution of radioactivity by the outgrowing hyphae was so great that insufficient activity was produced in the volume being scanned to enable detection.

Regarding the first point no information could be found in the literature on whether fungi in general are capable of translocating cobalt 60 or caesium 137 in a manner similar to that reported for higher plants as regards caesium 137¹¹ and cobalt 60¹². It was therefore necessary to study translocation in fungi in agar and broth cultures.

Beginning these studies with *P. filamentosa* the transport of cobalt-60 from submerged into aerial mycelium was studied by autoradiography employing Pelco's¹³ stripping film technique. Cobalt is often considered to be a microbial toxin. However the addition of cobaltous chloride to the medium—whether as the stable or the radioactive isotope—enhanced the growth of *P. filamentosa*. Details of the experimental technique were described by Grossbard¹⁴, who suggested that accumulation of cobalt 60 occurred inside hyphae submerged in radioactive agar, for as the autoradiograms showed, the density of silver grains inside the hyphae was greater than in the agar film between the mycelium. Yet, in autoradiograms of aerial mycelium growing just above the active submerged mycelium the grain density within the aerial hyphae was similar to that of the background. This suggested that the tracer was not transported into the aerial hyphae. Similar negative results were obtained from aerial mycelium in broth cultures. It was therefore at first believed that *P. filamentosa* inherently lacked the capacity for transporting cobalt 60 through its system and was one of the group of fungi which—after Schütte¹⁵—had no translocation mechanism. However, when using the stripping film technique very thin preparations have to be made and a few hyphae only were used. The absence of silver grains in the aerial mycelium may have been due merely to the fact that the dilution of the nuclide when transported from the submerged into the aerial hyphae was so great that not enough tracer was available for a positive autoradiogram to be formed. That this reasoning was correct was shown when an autoradiogram was produced of large quantities of mycelium placed on an X-ray film. Adapting a technique described by Schütte¹⁵ a small dish of agar containing cobalt 60 was placed

Fig 1 Autoradiogram of *Pellicularia filamentosa*, 'Cellophane strips + mycelium'
 > Original outline of container (diagrammatic) with agar + cobalt-60 and inoculum of fungus
 Arrow indicates inactive agar with fresh mycelium which became labelled with cobalt-60
 Gradual decrease in intensity of blackening with increase in distance from active container

inside a large one filled with similar but inactive agar. In the centre of the radioactive dish *P. filamentosa* was inoculated. The mycelium grew out of the dish over the glass edge on to some 'Cellophane' strips situated on top of the inactive agar of the outer container. The strips together with the mycelium were removed and fixed on microscope slides which in turn were placed in close contact with an X-ray film 'Industrial B' (Ilford). After exposure for 3 weeks a clear image of the mycelium developed, suggesting translocation of cobalt-60 from the inner container via the mycelium (Fig 1). The blackening was most intense at the points where the 'Cellophane' strips were nearest to the container with the radioactive agar and decreased in intensity with an increase in distance. However, when tufts of hyphae were removed from the 'Cellophane' strips at intervals of 5 mm the resulting autoradiograms were negative. These observations indicate that a translocation mechanism for cobalt-60 and probably other materials does occur in *P. filamentosa* but that it cannot be demonstrated readily in individual hyphae.

Translocation was then studied in some Phycomycetes, that is, in *R. stolonifer* and *P. blakesleeana*. These two fungi were grown in flasks with a layer of radioactive agar at the bottom. Individual sporangiophores or tufts were removed and fixed to a glass slide

with collodion and autoradiograms prepared. Figs 2a and b show the sporangiophores of *P. blakesleeana* labelled with caesium-137 and cobalt-60, respectively.

The sporangiophores as well as the sporangia of both fungi displayed considerable grain density giving rise to intense blackening which formed a true image of the morphology of the fungal structures. However, in the sporangia the blackening was far more intense. From these observations it was inferred that the nuclides were readily transported from a food base, frequently 5-6 cm away, through the sporangiophores and that they accumulated in the sporangia. It is tentatively suggested that the two nuclides were translocated by means of protoplasmic flow. Many workers have reported on this phenomenon in *Rhizopus* and other Phycomycetes and have observed that the direction of the protoplasmic streaming was towards the sporangia in which the protoplasm became concentrated prior to spore formation. The analogy with the movement of cobalt-60 and caesium-137 is thus apparent. Furthermore, Grossbard¹⁰ reported that where cobalt-60 labelled hyphal fragments of *Phytophthora cactorum* were ruptured, the tracer could be found in the cell content which had oozed out but not in the empty fragments. The fact that the translocation of cobalt-60 could be demonstrated in individual fungal structure far more readily in the aseptate Phycomycetes than in the septate *Pellicularia*, when using a medium with the same activity, provided further support for the hypothesis of transport by protoplasmic flow. Buller¹ has shown that both *R. stolonifer* and *P. filamentosa* displayed protoplasmic streaming, but he postulated that the type of streaming and the rate differed because of the presence of septa in *Pellicularia*. The flow passed only via a single pore in the septum and thus was slowed down, and this may have affected both the rate and efficiency of translocation. It seems likely that cobalt-60 is held firmly by the protoplasm and moves through the fungus only in chemical combination with the protoplasm (by co-ordination of cobalt with the amino functions of proteins, etc). This fits in with the results of Abelson and Aldous¹¹, who, working with cobalt-59, showed in the case of *Escherichia coli* that the nuclide was "very tightly bound, within the experimental error no tracer was lost by either the exchange with magnesium or inactive cobalt". They suggested as one alternative a "non-specific, non-metabolic attachment to the proteins and other groups of the organism". Thus, if cobalt-60 is transported through the mycelium it is assumed that it is carried along by the protoplasm as an integral part of it.

Fig 2 Photographs of autoradiograms of sporangiophores of *Phycomyces blakesleeana*
 a Stripping film technique. Inactive preparation is merely a photograph of the actual slide while the labelled shows intense blackening especially in the sporangia. b, Apposition on X-ray film. Inactive preparation formed no image at all.

The above results suggest that all the fungi tested display a translocation mechanism for the two nuclides in agar media though this is probably more efficient in the case of the Phycomycetes. Failure to detect radioactivity in the new mycelium growing from a labelled inoculum in the soil cannot therefore be explained satisfactorily in terms of an inherent lack of a translocation mechanism in the fungi tested.

While the scanning technique with the scintillation counter could be depended upon to locate a radio active inoculum in the soil, it may not have been sensitive enough to trace small alterations in the distribution of activity, especially in view of the fact that the strong radiations emitted from the inoculum may obscure any small change in counting rate due to genuine radioactivity. Having established that both *P. flamentosa* and *R. stolonifer* have the ability to translocate cobalt 60, a more direct method for testing transport via the fungi in the soil was employed. The soil columns after incubation for several weeks were cut into sections of 2.0 cm. in the case of *P. flamentosa* and 4 and 6.0 cm., respectively, in the case of *R. stolonifer*. Aliquots of 0.5 gm. of soil of each section were extracted with concentrated nitric acid (10 ml.) and the extract counted in a standard G.M.C. liquid Geiger counter tube (Table 2). In addition a very thin smear was made on a glass slide of 0.5 gm. of very finely ground soil taken from each section, placed on an X ray film backed with a 1/16 in. lead sheet and exposed for 3 weeks. Figs. 3a and b show a representative photograph and corresponding autoradiogram of a preparation and Table 2 summarizes the results.

From both the counts and the autoradiograms, it can be concluded that some slight migration of the nuclide occurred from the soil section containing the inoculum but over a short distance only. This was observed both in the tubes with the killed and living inoculum. Frequently though not always movement of cobalt 60 tended to be greater from the killed inoculum. This may be explained in terms of increased permeability of fungal cells after death. As the inocula consisted of disks of agar cultures the nuclide might also have diffused from the agar and not from the fungal structures only. The agar disks were used, because by providing a food base the subsequent growth of the mycelium was greatly enhanced. Other inoculation methods such as by washed mycelium from a broth culture are under investigation in order to eliminate this complication. What migration has taken place may be interpreted on one hand as diffusion of the nuclide from both the agar base and the mycelium and then through

Fig. 3. Photograph (a) and autoradiogram (b) of soil smears from a soil growth tube of *Rhizopus stolonifer* (killed inoculum cobalt-60). Soil with inoculum gives the most intense image; a true reproduction of the soil smears. At a distance of 4 cm. the image is much weaker and at 6 cm. none is formed.

the soil, or else as a case of genuine translocation. There is some indication that the migration rate was somewhat slower in *Pellicularia* than in *Rhizopus* since in the former activity was rarely found farther than 2 cm. from the inoculum. An analogy with the more efficient translocation mechanism of *Rhizopus* as observed in agar culture suggests itself but further confirmatory experiments are necessary before drawing final conclusions, for the migration rate is dependent on many environmental factors not easily standardized. Whatever the mechanism of the

migration of cobalt-60 and whatever the difference in rate between killed versus living inoculum or *P. filamentosa* as compared with *R. stolonifer*, the percentage of cobalt-60 and the distance over which it is transported are very small indeed. In every case most of the activity is retained in the section of the soil containing the inoculum. There the nuclide may be held by either adsorption on the soil colloids after having diffused through the cell wall of the fungi or within the hyphae of the original inoculum, possibly bound to the protoplasm.

Regarding the first point, this would fit in with the observation of Jones *et al.*¹⁵, who have shown that in a soil with moderate exchange capacity cobalt-60 remains close to the surface even after repeated applications of water. These workers placed the cobalt-60 directly in the soil, while in the experiments described here it was introduced via the fungal inoculum, the soil used was one of moderate exchange capacity.

On the second possibility, Harley and McCready⁶ have shown that in the case of excised mycorrhizal roots of the beech 90 per cent of phosphorus-32 absorbed from aerated media was found to be held in the fungal sheath and only 10 per cent diffused into the core. This ratio varied with environmental conditions⁶. By analogy it could be assumed that cobalt-60 also is firmly held within the fungal tissue, especially in view of the observations that migration is of lower order from the living than from the dead inoculum. Thus, the possibility is not ruled out that the small migration which had occurred from

living inocula was due to some extent to active transport inside the fungal tissue, perhaps by protoplasmic flow. This is a hypothesis, and more work is required to distinguish between migration by diffusion or by active translocation. Probably both factors will operate simultaneously.

Our thanks are due to Dr William Davies for his interest in this work, for encouragement and guidance and for providing facilities to carry out these studies. We are indebted to Mr G. E. Barton for his valuable collaboration and technical assistance, without which this work would not have been possible, and to Mr D. Smith for the preparation and counting of soil extracts.

OBITUARIES

Prof Kaj U. Linderstrøm-Lang, For Mem. R. S.

THE death of Prof. Kaj Ulrik Linderstrøm-Lang on May 25 was a great and irreplaceable loss, not only to his colleagues and friends but also the scientific community at large. The Chemical Division of the Carlsberg Laboratory in Copenhagen, which he led with such force and inspiration for twenty-one years, is perhaps unsurpassed in terms of the number of individuals who identify it as a major scientific home.

Linderstrøm-Lang was born in Frederiksberg, Copenhagen, in 1886, the son of Dr C. F. Linderstrøm-Lang. His education at the Danmarks tekniske Højskole led to a degree in chemical engineering in 1919, following which he became assistant to Prof. S. P. L. Sørensen at the Carlsberg Laboratory. In the environment of Sørensen's fundamental research on the physical chemistry of proteins in solution, Linderstrøm-Lang's natural talents for mathematics and laboratory experimentation led him to conceive in 1925 his classical paper "On the Ionisation of Proteins", which stands to-day as the fundamental theoretical treatment of protein titration curves.

During the period 1926-27 he studied in the laboratory of Prof. R. Willstätter in Munich, and there he developed his continuing interest in the chemistry and mode of action of proteolytic enzymes. Upon his return to Copenhagen he completed his earlier investigations on the electrophoretic properties of proteins and presented his doctoral dissertation in 1929.

His investigations of the nature and determination of proteolytic enzymes, developed in collaboration with the increasing flow of visiting scientists in the Laboratory, became directly applicable to the work

he afterwards undertook in collaboration with Dr. Heinz Holter, who went to the Laboratory in 1930. Linderstrøm-Lang and Holter developed, over the succeeding ten years, a tremendous array of delicate and sensitive techniques for the study of the distribution of a large variety of enzymes and other constituents in cells. These micro methods, now standard procedure in many laboratories throughout the world, made possible an enormous advance in our understanding of many aspects of cellular physiology. It is characteristic of the methods that Linderstrøm-Lang developed that they were based on extremely simple but basic physical principles. Well-known examples are the Cartesian diver technique for the measurement of metabolism in single micro-sections of tissue or of individual cells, and the extremely sensitive gradient technique for the determination of the densities of minute quantities of material. A whole generation of young chemists and biologists was strongly influenced by these methods and profited enormously by direct collaboration with Linderstrøm-Lang during this period of his scientific career.

When S. P. L. Sørensen retired in 1938, Linderstrøm-Lang was chosen as director of the Carlsberg Laboratory. Continuing along the lines begun by Sørensen, which had already made the Laboratory world-famous in protein chemistry, Linderstrøm-Lang initiated an outstanding series of studies on the internal structure of protein molecules. Using as probes such phenomena as the volume contraction occurring as a result of proteolytic cleavage of peptide bonds, he began to develop during this period his strong interest in the limited modification of proteins as one means of elucidating internal structure, and

published many fundamental papers on such systems as the conversion of chymotrypsinogen to chymotrypsin and ovalbumin to plakalbumin. An example of his inexhaustible ingenuity in the development of experimental techniques was the 'deuterium exchange' technique, which permitted the estimation of the relative rates at which individual hydrogen atoms within the primary, secondary and tertiary structures of a protein molecule could reach equilibrium with deuterium atoms in the water in which the samples were dissolved.

Linderström Lang's scientific talents, combined with his characteristics of warmth and perception, brought him early and frequent recognition by many organizations both scientific and civic. In addition to receiving numerous honorary degrees from universities throughout the world, he was a member of the Royal Swedish Academy of Sciences, the Academy of Sciences of the U.S.S.R., the Royal Society of London, the Finnish Scientific Society and the National Academy of Sciences of the United States, to mention only a few. He was, at various periods during his life, president of the Danish Academy of Technical Sciences, the Akademiet for de tekniske Videnskaber, and in 1958 of the International Union of Biochemistry.

The list of honours and accomplishments scattered through his career are too numerous to list in detail. Perhaps even more important than these tangibles, however, was the impact of his warm personality on everyone who knew him. Kaj Linderström Lang had talents in many areas of human endeavour and, had he not chosen science as his major interest, could clearly have contributed prolifically in a variety of pursuits including music, art and literature. Those who know him will not forget his unique combination of wisdom, humour and intellectual integrity. With his death the world lost not only a great scientist but also a great man. C B ANDERSEN, JYU

Dr M Copisarow

MAURICE COPISAROW, who died on April 16, in his seventieth year, was a scientist of quite outstanding ability. His university education was acquired between 1909 and 1913 in the School of Chemistry at Owens College, where I knew him as a fellow student. He stayed on for postgraduate study as Dalton Research Scholar during 1914-16, working with Chaim Weizmann on "Phthalides of the Benzene, Naphthalene and Carbazole Series" (published in 1915). Afterwards, as Honorary Research Fellow (1916-19) he launched out into independent inquiries concerned mainly with reactions promoted by aluminium chloride.

During the First World War, Copisarow worked for the Ministry of Munitions and was responsible for a change in the method of washing TNT which greatly reduced the risk in handling this explosive. At the end of the War he experimented on the conversion of various explosives and also phoagens into products for which industrial uses could be found, and in these operations his eyesight suffered severe injury. Most unpleasantly the damage was progressive and in a relatively short time, while still at the outset of his career, he became blind. However, by 1925 he had to his credit nineteen publications of high quality, and in that year he was awarded the D.Sc. of the University of Manchester.

In his work as a chemist he could never have confined himself to narrow specialization. His mind

ranged over whole fields of scientific activity, and his keenness of perception allied to his uncommonly active imagination gave rise to a versatility which is well exemplified by his generalized theory of allotropy (*J Chem Soc*, 1921) and by his work on the phenomenon of periodic precipitation, reported between 1927 and 1932 in various scientific journals. These publications illustrate admirably his ability to recognize certain apparently unrelated chemical processes and structures as forms of expression of a unifying principle and to enunciate it.

After he had lost his sight, Dr Copisarow's scientific activities became restricted principally to the preparation of review articles and essays dealing with matters calling for theoretical consideration. His blindness seemed indeed to intensify his insight, and he extended his thinking to such subjects as the functioning of certain oxidation enzymes, the effects of radiation on enzymes and the biochemistry of virus infection. He studied these matters with the ultimate object of selecting and co-ordinating knowledge which might throw light on problems associated with the malignant growth of cells. Observations on biochemical work in the field of cancer research were published over a period of years in several journals, including a comprehensive review on the "History of Human Cancer", which appeared in the *Edinburgh Medical Journal* in 1952. Copisarow's writings on these matters were prompted by his great desire to contribute all he could to the furtherance of progress in the war on disease.

Further evidence of his feeling for the well being of his fellow-countrymen is afforded by the interest he had in the application of appropriate scientific knowledge to agricultural pursuits, and during the Second World War he was active in advising on methods for grassland improvement and for the reclamation of bracken-covered areas. In all he published eighty-three scientific papers and in recognition of special services to his country he was placed on H.M. Civil List.

Dr Copisarow was a man dedicated to the work he had chosen, and though in later years, he had to endure much ill health and many worries, he remained courageous in adversity, sustained to no small degree by religious faith and by the devotion of his wife and family. T K WALKER

Dr D S Gracie

VOLUNTEERING in the Royal Scots at seventeen, David Smart Gracie was badly wounded on July 1, 1910 at the Somme, and spent the rest of the First World War as a prisoner in Ruhleben, an experience which marked him for life.

In the late 'twenties, after graduating at Edinburgh with a medal and lecturing on agricultural chemistry, he went to the Colonial Service and carried out a notable "Preliminary Survey of the Soils of Kenya" before the Colonial Agricultural Service had been reconstituted.

Moving to the Egyptian Ministry of Agriculture in 1930, Gracie spent two decades investigating the fascinating problems presented by a soil which has sixty centuries of cultivation history, capped by its change to irrigation all the year round during the past hundred years. As the last survivor within that Ministry in 1949 of what had once been a strong team of some twenty British scientific expatriate workers, he finished with a chattering Brinsgale by collating

and analysing his results from sixteen continuous years of field experiments on the cotton crop. One side-issue during the Second World War from his work on other crops was to economize tonnage of merchant shipping by showing that imported artificial fertilizers produced much more food for the Egyptian than grain imported as such, which the British army had to bring in for its own use.

In 1949 Gracie started afresh in the dusty precincts of Amman with scanty resources, locating cultivable areas in the Jordan valley and the desert for the United Nations Arab Relief. In 1955 he transferred to Iian with better resources, where he created a large efficient laboratory organization for the United Nations Technical Assistance Board at Teheran. In 1958 he broke down from heat exhaustion, and retired to his Edinburgh home too late, dying there on May 31 of this year, leaving his wife Vera and one son.

With all his work done overseas, in countries not notorious for gratitude, merely increasing the resources of those countries by many acres of cultivation or many more tons of annual crop, he is likely to be one of those for whom there is but little remembrance—a depressing reflexion on those fine political projects for under-developed countries.

Gracie has been described as “a fierce seeker for truth, who could never suffer a rogue gladly”, though he might tolerate a fool. He held on to his standards of precision, and made sure that his native assistants did the same.

Out of thirty years joint experience, a mutual friend writes of “the qualities of integrity, judgment, and application in good and indifferent health which he brought to his work. He had none of the narrowness with which specialists are sometimes charged, he was widely read in a diversity of subjects and worth listening to on any of them. Unbending in his uprightness with an inner light which lit for him so clearly the path he held in all affairs, yet he was not stiff, human, kindly, generous, and considerate, his friendship was one of the wholly good things a man could be blessed with.” W. LAWRENCE BALLS

Dr W W Francis

DR WILLIAM WILLOUGHBY FRANCIS, librarian of the Osler Library at McGill University, Montreal, since 1929, died on August 10, aged eighty-one. A relative of Sir William Osler (his mother was Osler's first cousin, and Osler always spoke of him as a nephew), he was born at Montreal on April 2, 1878, and was educated at Trinity College School, Port Hope, and at Johns Hopkins University, Baltimore, where he graduated A.B. in 1898 and M.D. in 1902. After further study in Montreal, Baltimore, Vienna and London, he returned to Montreal in 1906. In 1912 he was appointed assistant editor of the *Canadian Medical Association Journal* and secretary-treasurer of the Canadian Medical Association, and in 1915 he went overseas with No. 3 Canadian General Hospital (McGill) as registrar. On demobilization in 1919, he lived in Oxford (where Osler was regius professor of medicine) before he became editor of the *International Journal of Public Health* at Geneva.

Dr Francis's *magnum opus* was started in 1922, when he joined R. H. Hill, Archibald Malloch and Leonard Mackall in compiling the catalogue of Osler's magnificent library at Oxford. Working for 14–16 hr a day for seven years, he succeeded nobly in inter-

preting Osler's dream of an ideal biobibliography of epoch-making books and in staging it as a pageant. The catalogue under the title “*Bibliotheca Osleriana*” was published by the Oxford University Press in 1929, and the Osler Library at McGill was officially opened on May 29 of that year. Dr Francis was president of the Medical Library Association during 1935–37, and honorary consultant to what was then called the Armed Forces Medical Library at Washington.

Bearing a striking resemblance to Osler in the shape of his head, his olive complexion, his dark, humorous eyes, the lightness of his step, and several of his mannerisms, ‘Bill’ or ‘Billy’ Francis was a charming man. Someone said of him that he was born under a dancing star and sang his way through life. His learning was vast and bizarre, but never pedantic, his memory was rich and retentive, his humour was spicy and puckish. His seemingly infinite leisure was at the disposal of the young and old who went to him for inspiration and for help. A classical scholar, a painstaking bibliographer (“his meticulousness exceeds anything you ever met with”—Osler), and an unsurpassed writer of whimsical letters, Dr Francis married in 1921 Hilda Colley, who survives him, with his daughter, Dr Marian Kolen.

W. R. BETT

Prof A Preece

THE William Cochrane chair of metallurgy in the University of Durham at King's College, Newcastle upon Tyne, became vacant last November with the untimely death of Prof Archibald Preece at the age of fifty-three.

Preece was educated in South Wales and graduated from University College, Swansea, in 1926. He first joined the Pressed Steel Company of Great Britain as metallurgist, and later became a research officer to the South Wales Siemens Steel Research Association, but he returned to academic work in 1933 when he became a lecturer in metallurgy in the University of Leeds. There he pursued researches on the effect of high temperatures upon steel. The importance of his work was recognized by the award of the Sir Robert Hadfield Medal by the Iron and Steel Institute and by his promotion to a readership in the University of Leeds in 1946.

In 1948 he was appointed to succeed C. E. Pearson as professor of metallurgy in King's College, Newcastle upon Tyne. He took charge of a small but active department of teachers and research workers who carried out important work on the scaling of metals, temper brittleness and the solidification of steel castings, which were Preece's particular interests, though he encouraged others to work on a wide variety of different metallurgical topics. Just before his death he had the satisfaction of moving his Department into more commodious quarters and installing new equipment.

Prof Preece was a deeply religious man who could be stern or kindly as the occasion demanded. He set himself extremely high standards both in his work and in his dealings with students and colleagues. Probably the most outstanding quality by which he will be remembered was his unwavering integrity and his strict adherence to the truth as he saw it. He was deeply devoted to his work and to his Department, and his sudden death was a great loss to all who came in contact with him.

A. F. BURSTALL

NEWS and VIEWS

Commonwealth Scientific and Industrial Research Organization Dr F W G White CBE

Dr F W G WHITE, deputy chairman of the Commonwealth Scientific and Industrial Research Organization Australia, has been appointed chairman in succession to the late Sir Ian Clunies Ross. Dr White who is a New Zealander, went to Australia in 1941 at the invitation of the Commonwealth Government to help in Australia's effort to provide radar equipment for the Australian and United States Forces. When the Organization was formed in 1949 he became chief executive officer, and in 1957 deputy chairman. During the period of reconstruction following the War Dr White played a leading part in building up the laboratories of CSIRO, which have since then assisted in the growth of Australia's secondary industries. He was largely responsible for the establishment of laboratories for meteorological physics, coal research and building research. He has been active in sponsoring the formation of industrial research associations and in helping firms to create their own research facilities. Dr White has taken a direct interest in the development and work of the Organization's laboratories concerned with biological research and has travelled widely to study agricultural and pastoral problems at first hand. Since 1946 when special funds were made available for wool research he has devoted a considerable effort to the founding and development of the CSIRO Wool Research Laboratories, which have done much to sustain wool in the competitive fibre markets of the world.

Dr White graduated as MSc in 1928 in the University of New Zealand and later went to do research work at the Cavendish Laboratory, Cambridge. He was awarded the PhD degree of the University of Cambridge in 1932. After a period as a University teacher in the University of London, he was appointed professor of physics at Canterbury University College in New Zealand.

Dr R. N. Robertson

Dr R. N. ROBERTSON, a distinguished Australian plant physiologist has been appointed a full-time member of the executive of the Commonwealth Scientific and Industrial Research Organization in succession to Dr F W G White. Dr Robertson is an outstanding research worker who has an unusually wide interests in both basic and applied aspects of plant physiology. Many of the complex problems facing the farmer and the fruit-grower can only be solved if we know how the plant functions—how it absorbs minerals from the soil and how it uses them to build up its structure. Dr Robertson has been concerned with these basic problems throughout his career and particularly in his present position as leader of the Plant Physiology Research Unit jointly operated by the Division of Food Preservation and Transport of the Commonwealth Scientific and Industrial Research Organization and the University of Sydney. Work by Dr Robertson and his colleagues on the growth and development of apples has led to an understanding of the reasons for the poor keeping quality of large fruit and fruit from light crops. His

investigations on the maturity of pears have been of particular importance to the vegetable canning and freezing industries. During the Second World War Dr Robertson gave valuable help to the food control authorities through his investigations on the causes of heating in stored wheat. Dr Robertson has spent the past year as visiting professor of horticultural science at the University of California and is at present on a short visit to the University of Cambridge.

Dr Robertson was born in Melbourne in 1913. He graduated in science with first-class honours in botany at the University of Sydney in 1933 and continued postgraduate research at that University as Lunnan Macleay Fellow. He was awarded a research scholarship of the Royal Commission of the Exhibition of 1861 and went to work at the University of Cambridge, receiving the PhD degree for research in plant physiology. In 1945 he joined the staff of the Division of Food Preservation and Transport of the Commonwealth Scientific and Industrial Research Organization and took charge of work on the storage of fresh fruit and vegetables. When a Plant Physiology Research Unit was formed in 1952 as a co-operative venture between the Division and the Botany School of the University of Sydney, Dr Robertson became its leader. Dr Robertson is a Fellow of the Australian Academy of Science and a corresponding member of the American Society of Plant Physiologists. The Royal Society of New South Wales awarded him its Clark Memorial Medal in 1954. For many years Dr Robertson was secretary to the Australian National Research Council.

Agricultural Chemistry in Aberystwyth

Prof R O Davies

PROF DAVIES has retired from the chair of agricultural chemistry, University College of Wales Aberystwyth. His services to the University College of Wales and to the agricultural industry of the Principality have extended from 1920 when he was appointed lecturer in agricultural chemistry, in 1939, he became head of the Department of Agricultural Chemistry in the College, which then also served as the agricultural advisory centre for the Mid Wales area. On the establishment of the National Agricultural Advisory Service in 1946 he relinquished his post as advisory chemist and devoted his activities wholly to College work and to his interests in research.

Prof Davies has been especially concerned with problems of the nutritive values of lowland and upland swards and of milk composition, particularly in relation to their mineral constituents. His early work with A L Provan and W J Pugh established that an increase in the protein and mineral constituents of milk occurred when cows were changed from winter rations to lowland pasture. Experimental work on upland swards with W I J Milton (of the Welsh Plant Breeding Station) was begun in 1930. It shows that the mineral deficiencies of these swards can be rectified without resort to ploughing and reseedling. Long term treatments of upland swards have led to the extinction of the native hill herbage and its replacement by species of high productivity and mineral content which have become established.

voluntarily in the favourable environment created through the improvement of soil status and the control of the grazing animal. More recent work with D I H Jones has shown that the mineral content is one factor that influences the nutritive value of the organic nutrients in upland swards, and that the digestibility and the utilization of the digested nutrients of unimproved hill herbage can be increased by feeding calcium carbonate with the grass.

Prof T W Goodwin

PROF R O DAVIES has been succeeded by Dr T W Goodwin, who since 1949 has been senior lecturer in biochemistry in the University of Liverpool. Dr Goodwin's early work on vitamins A and C has led on to a wide interest in the biosynthesis of carotenoids and in comparative biochemistry, in these fields, the range of his own studies and those in co-operation with other workers has formed the basis of notable developments as well as for a wide series of reviews and contributions to reference texts. He has had considerable opportunities of contacts with overseas research in his own particular and cognate fields of plant biochemistry, having held a Rockefeller Foundation travel grant in 1954, when he worked in the University of California with Profs Fox and Mackinney, visited many other American universities, and later having taken part in symposia and lectured in several of the leading research centres in European countries. At Liverpool he has been concerned in the presentation of fundamental and applied biochemical principles, not only to honours BSc students but also in the schools of medicine, dentistry and veterinary science. Dr Goodwin's wide experience in teaching and research will enhance the resources of the Rural Science Departments at Aberystwyth, which, with the closely associated Welsh Plant Breeding Station, have long had special interests in problems of crop, grassland and animal production.

British Gelatine and Glue Research Association :

Dr D A Sutton

DR D A SUTTON, chief biochemist of the South African Council for Scientific and Industrial Research Pneumoconiosis Research Unit at the South African Institute of Medical Research, Johannesburg, has been appointed director of research of the British Gelatine and Glue Research Association in succession to Mr A G Ward, who is going to the University of Leeds as professor of leather industries (see *Nature*, 182, 1707, 1958). Dr Sutton graduated with first-class honours in chemistry at the Imperial College of Science and Technology, London, and after holding posts with the British Rubber Producers' Research Association and the Paint Research Station, went to Pretoria in 1949 where, until 1956, he was head of the Division of Organic Chemistry of the Council for Scientific and Industrial Research, in charge of groups working on various aspects of industrial organic chemistry. He has since been in charge of investigations of the collagen in various living constituents, the chemotherapy of silicosis, and carcinogen liver protein bonding.

Uranium as Fuel

GREAT BRITAIN's nuclear power programme is based on the Calder Hall type of nuclear reactor which 'burns' natural uranium as fuel. Uranium ore is mined in Australia, South Africa, Canada and the United States and processed to an oxide known as 'yellow cake'. Material from the Commonwealth

is shipped to Great Britain and processed at the Springfields factory of the UK Atomic Energy Authority into uranium metal and then into fuel elements for British reactors. A special feature of the March 1959 issue of *Atomic World* (10, No 3) is a series of three articles linked by the theme "From Mine to Fuel Element, 1959", in which the procedure from the initial mining of the uranium ore to the final fabricated fuel element is described. In the first article, "Mining and Processing at the Mary Kathleen", the mining and treatment of the ore to the 'yellow cake' at the recently completed £13 million installation at Mary Kathleen in Australia is considered. This is followed by an account of the processing at the Springfields factory where new plant is being commissioned, and the final article in the series, entitled "Fabricating the Fuel Elements", describes how the billets of natural uranium are cast into rods which are then machined, heat treated and canned in 'Magnox' (an alloy of magnesium and aluminium) to give the fuel elements used at Calder Hall and Chapel Cross. The complete series of operations has been summarized in a composite flowsheet drawn by the staff artist of *Atomic World*. The drawing, 11 in. x 22 in., is very suitable for use in science sixth forms in schools and in technical colleges, and copies may be obtained (price 2s 6d) from the publishers.

Time Ball at Greenwich

AFTER an absence of more than a year, the Time Ball has recently been erected on a new mast on the roof of Flamsteed House, the oldest of the Royal Observatory buildings at Greenwich. A time ball was first erected there in 1833 and it was in 1919 that the aluminium sphere now used was fitted. It was taken down for overhaul in 1958 and as the operating machinery is not yet complete it is not intended to resume daily dropping until the summer of 1960, when Flamsteed House will be opened to the public as an annex of the National Maritime Museum.

The Ageing Worker

IN a report recently published by the Nuffield Foundation ("Age and the Working Lives of Men: an Attempt to Reduce the Statistical Evidence to Its Practical Shape") Studies of Ageing within the Conditions of Modern Industry. Pp 68. London: Nuffield Foundation, 1959. 3s net.) F Le Gros Clark, who has been responsible for a number of monographs on ageing, has addressed himself to answering, as best as present evidence permits, the question, what happens within the conditions of modern British industry to ageing men when failing powers make them no longer fully employable on their normal work. He is concerned, that is to say, not with the psycho-physiological aspects of ageing and the changes that take place in the ageing organism, but with the sociological aspects—the fate of ageing individuals in the contemporary industrial milieu. Reliable evidence on this topic is remarkably hard to come by, and Mr Le Gros Clark has made skilful use of the available statistical data to arrive at his tentative conclusions. Total incapacity for work increases steadily from the age of 55 onwards, and by the age of 65 about 10 per cent of all male workers are totally incapacitated. By the age of 70 this percentage has approximately doubled. The real industrial problem, however, concerns men who are still fit for work, but who because of failing powers need different and less exacting work. At the age of

65 the author estimates that some 20 per cent fall into this category, while a smaller but still considerable number need alternative work well before their mid sixties. There are, of course, wide differences between occupations and the report provides some provisional data relating to thirty occupational groups. The Report suggests that an important question is whether an increasingly mechanized industry will be able to provide the kind of work needed by ageing workers and by those who do not wish to retire at 65. If not, what other social arrangements will be needed to ensure the well being of the ageing man?

Staff for Industry and Commerce

Two important publications dealing with the control and development of staff in industry and commerce have been issued by the Institute of Personnel Management. The first, by E. M. Barling, late director of personnel of the John Lewis Partnership, is concerned with the management of workers whose skills are mainly mental or social rather than manual. Much of the practice described by Miss Barling will be of interest to those dealing with similar problems in large industrial and commercial organizations, Government departments, public corporations, hospitals and scientific establishments. The subjects covered include training and education, pay and incentives, consultation and communications and welfare amenities (Pp 46 London Institute of Personnel Management, 1959 4s 6d). The second, by F. I. de la P. Garforth, of the Department of Work Study and Staff Training, Engineering and Allied Employers' West of England Association, provides a systematic approach to the provision of supervisors and managers. The subjects covered in the broadsheet include organization charts, staff reviews and appraisals, forecasts of vacancies, recruiting policy, further education and training for staff, job rotation and exchange and a section on the initiation and operation of a systematic management development policy (Management Development: A Systematic Approach to the Provision of Supervisors and Managers Pp 72 London Institute of Personnel Management, 1959 15s 6d).

I.C.S.U. Review

The activities of the International Council of Scientific Unions have greatly expanded during recent years. Joint Commissions have been appointed covering fields of interest common to two or more of the constituent unions and other committees have been formed to organize specific programmes of research. The recent International Geophysical Year was initiated and sponsored by the Council through a special committee appointed to supervise the programme. Despite these outstanding achievements there is still widespread ignorance concerning the organization and activities of the International Council of Scientific Unions. The lack of adequate information concerning its affairs has been felt to be detrimental to the continued growth of the Council. As a step towards remedying this state of affairs and with the view of encouraging the flow of information between individual unions the Executive Board of the Council has approved the establishment of a new quarterly journal to be called the *I.C.S.U. Review* to provide information to members of the Council and to all who are interested in international co-operation in science about the activities of the Council and of the scientific unions. The *I.C.S.U. Review* will contain

reports of meetings of the Bureau, the Executive Board and the General Assembly of the I.C.S.U., information about special activities, reports of some of the more important symposia, reviews of certain publications, special articles on various aspects of international co-operation in science, and announcements about forthcoming meetings, symposia or congresses organized by the unions. In the first issue (May 1959) Pp 1+50 Subscription 16 florins 30s or 4.50 dollars per volume of four issues. Amsterdam: Elsevier Publishing Co., 1959. Prof A. von Muralt, treasurer of the International Union of Physiological Sciences and former president of the International Council of Scientific Unions, has written an article entitled 'What does ICSU stand for?' There are other articles on international collaboration in science by L. V. Berkner, on the International Geophysical Year by Prof Sydney Chapman on the marine sciences by Roger Revelle, and a review of some aspects of the origins of life considered in the light of the Moscow international symposium of August 1957, by N. W. Pirie. With the increasing importance of international co-operation in science in recent years, and the growing status of the International Council of Scientific Unions as an essential part of the organization of scientific activities on a world wide scale the *ICSU Review* will undoubtedly fill an important niche in the literature of science, and will find a place on the shelves of all scientific libraries and information services.

Russian Journal of Inorganic Chemistry

A TRANSLATION of the Russian *Zhurnal Neorganicheskoi Khimii*, the only Russian journal devoted exclusively to inorganic chemistry, is being published by the Chemical Society, under the title *Russian Journal of Inorganic Chemistry*. In an introduction to the first number the President of the Chemical Society states that it marks a further step in a plan to make Russian chemical literature more generally available. Many chemists have become aware of their loss in being unable to read in the original the numerous important scientific papers now being published in the U.S.S.R. Although increasing attention is being paid to the teaching of Russian, the need for English translations will inevitably persist for a long time. The publication has been made possible by the far-sighted support of the Department of Scientific and Industrial Research. The Council of the Chemical Society believes that the venture will not only be of direct value to many research workers, but that it will serve to strengthen still further the sense of international partnership in the advancement of chemical science. The translation is by experts. The distributors are Cleaver Hume Press Ltd., 31 Wright's Lane, London W 8. The ordinary subscription rate is £30 (90.00 dollars in the United States) per annum to libraries of universities and technical colleges £22 10s (67.50 dollars in the United States) in both cases inclusive of postage. The first number has 103 pages in the large format of the *Journal of the Chemical Society* and includes thirty-nine papers and eight brief communications in all cases in full. The topics cover a wide range of interests in inorganic chemistry, some of the papers bordering on physical chemistry, and the standard is high. As indicating the general interest of the journal, mention may be made of one paper in which a MnS is shown to be photo-oxidized during the recording of the powder X-ray pattern and the published data on a Mn^{4+} are wrong.

Digest of Soviet Technology

A *Digest of Soviet Technology* is being published each month by Engineering Information Services, Ltd (No 1, April 1959 8 Victoria Road, Kirkham, Preston). The subscription rate is £6 6s annually. Such a new digest, with an editorial policy of giving "express information on recent technological developments in the Soviet Union and Eastern Europe", should be of great value to all persons concerned with technical progress in industrial and academic research. It is claimed that the information supplied is obtained by critical reading of a large number of periodicals and non-periodical literature published in Soviet countries. The fields of coverage are essentially mechanical engineering, production processes and methods, instruments and automation. The material is divided into the following sections: Design and Production, Metallurgy, Welding and Foundry Production, Instruments and Automation, General News, including inventions and book reviews. In the third number (June), the editors state that in future greater attention will be paid to 'non-periodicals'. This follows when one realizes that a considerable proportion of Soviet technical information is given in books before it appears in periodicals. Certainly when this policy is brought into force the *Digest* will be able truly to provide "express information".

Journal of Research of the National Bureau of Standards

It is announced in the April issue of the *Journal of Research of the National Bureau of Standards* that the Journal is now to be published in four separate sections. Section A (Physics and Chemistry), to be issued bi-monthly, will cover a broad range of physical and chemical research, with major emphasis on standards of physical measurement, fundamental constants, and properties of matter. Section B (Mathematics and Mathematical Physics), to be issued quarterly, will be devoted to pure and applied mathematics, including mathematical statistics, theory of the design of experiments and numerical analysis, theoretical physics, chemistry and engineering, with emphasis on the mathematical content, and logical design, programming, and computers. Section C (Engineering and Instrumentation), to be issued quarterly, will include new developments in instrumentation, data processing, test methods, and some of the work in acoustics, applied mechanics, building research and cryogenic engineering. Section D (Radio Propagation), to be issued bi-monthly, will report research in radio propagation, communications, and upper atmospheric physics. The separate sections may be subscribed for individually.

British Scientific Instrument Research Association Publications

It is announced in a recent issue of the *Bulletin of the British Instrument Research Association* that several changes are to be made in the regular publications of the Association. Henceforth, the *Bulletin*, *Stra Technical News* and *Research Reports*, together with other office matter, are to be printed by the Association. For this purpose an office type composing machine (supplied by Vari-Typer Ltd, London) and a Rotaprint rotary printing machine have been installed. The type faces used for the *Bulletin* and the *News* will differ from those at present, but the 10-point size will be retained. The

Bulletin, which was originally intended to be circulated to members of the Association only and which now is generally available, contains abstracts from current literature relating to the construction and use of scientific instruments, and news of the Association's activities in a section entitled "Association Notes". However, since March 1953, the second monthly publication, *Stra Technical News*, with a circulation limited to members only, has been issued, the specific aim of which is to tell the members about the Association's work. "Association Notes" will therefore, in future, be transferred from the *Bulletin* to *Stra Technical News*, and the title of the *Bulletin* is to be changed to *Instrument Abstracts*.

Feltmaking Research

THE eleventh annual report of the Director of Research of the British Hat and Allied Feltmakers Research Association for the year ended August 1958 (pp 20 Manchester British Hat and Allied Feltmakers Research Association, 1959) refers to the inclusion of research on finishing processes as a full time activity. Work on the carotting of furs has shown that the quality of the felt produced is related to the method by which it is obtained and further work has established the importance of body size, weight and build, relative to the size and substance of the hat. Work is to start on the stoving of skins in the carotting process and work on wool noils indicates that only 35 per cent of the overall variability of the felt-quality parameters can be explained by chemical tests for damage. Further work was carried out on the determination of the solubility in alcohol of grades of lac, and a study of a new multiroller machine for both settling wool and felting fur bodies indicates that multirollers can be made to give a rapid rate of felting without adversely affecting the quality of the felt, by using a balanced combination of pressure, jig amplitude and frequency, together with a pre determined traverse rate and controlled temperature and acidity. A detailed study was made of the technology of a fur-hardening machine as it affects the quality of the hardened forms and hat bodies produced, and in further work on the use of polyethanoxo compounds as dyeing assistants a relation was found between dyeing properties and the partitioning of the dyes into a layer of ethanoxo compound above water. Dyes with the highest partition coefficients gave the best results on dyeing. Studies on frictional properties of felt indicate that frictional behaviour against wood depends on the surface roughness, whereas against phenol-formaldehyde resins, the nature and structure of the fillers are important. Work was initiated on the measure of hat felts for tensile properties.

The Regional Research Laboratory, Hyderabad

THE annual report for 1957-58 of the Regional Research Laboratory, Hyderabad (pp ix+136 Hyderabad, 1958), emphasizes the further reorientation of the research programme both for team-work and the grouping of schemes into projects. For the internal planning and conduct of research the operational research approach has been followed, and this is outlined in the report. A striking feature of the year was the increase in pilot-plant work, and particular attention is also directed to the work on 'Citicide', a powerful new insecticide from turpentine developed in the Laboratory; on 'Hykole', active carbons produced from coke, the production of phenylacetic acid and phenylacetamide, for use in

the production of penicillin, and on 'Louniginin', a flavouring agent which has twenty times the strength of vanillin. Besides brief notes on progress in the various research schemes, arranged under some thirty project headings, the report includes notes on X-ray instrumentation and physico-chemical studies, analytical work, equipment and machinery, as well as a list of publications and patents, colloquia held during the year, and lists of research staff. Executive Council and Scientific Advisory Committee. Somewhat fuller details are given of the castor-oil project, which embraces the refining of the oil, the preparation of trimonoolein, using hexane as solvent, the hydrogenation of castor-oil and the preparation of surfactants, the cotton-seed project (including refining, storage, pilot-plant processing and hydrogenation to fatty acids), the fatty acids project, the dehydrated castor oil project, entomological studies on insecticides, the hand made paper project, the utilization of the products of low temperature carbonization of coal (including the preparation of pitch and road tar, preparation of creosotes for wood preservation, recovery of motor spirit recovery and fractionation of tar acids and their chemical examination) and the glass and ceramics development project.

Fencing Posts in Australia

MILLIONS of miles of fences divide and subdivide grazing and farm lands in Australia. Their construction, replacement and maintenance form a major cost item for primary producers. A survey carried out a few years ago by the Commonwealth Scientific and Industrial Research Organization Division of Forest Products, with the assistance of the State Departments of Agriculture, gathered essential information on materials, methods, costs, fence-life and causes of failure of fences on hundreds of farms across the country (Rural Research in CSIRO, 27 Melbourne, March 1959). Much of the cost is in the posts, and years earlier the Division had begun testing small, round, wooden posts to see if they would be suitable. After some thirty years trial they proved to be efficient if preserved against decay and insect attack by treatment with creosote. An alternative method of treatment using water-soluble preservatives has been developed more recently. The Postmaster General's Department has adopted full length preservative treatment for its telegraph poles and, as a consequence, expects an average saving of £2 million a year over the next forty years. This figure shows the savings that could be made if all farmers used round preserved posts for their fencing requirements. Those who are already using such posts have considerably altered their outlook on fencing. An important step in reducing fencing costs has been made. Other aspects, such as design, have been neglected and appear to offer fruitful fields for research.

Inflorescence Inception and Leaf Size in Gramineae

At BONNELL, in a study of the successive leaves on the flowering shoots of *Glyceria*, *Lolium* and *Triticum* has observed that the blades of successive leaves were progressively longer eventually reaching a maximum after which the blades of the last few leaves produced before heading were shorter. When the longest leaf blade was elongating, dissection of the shoot apices showed that inflorescence initiation was taking place. Epidermal cell measurements in *Triticum* indicate that differences in blade length are due to

differences in the amount of cell extension. It appears that a correlated change occurs in blade morphology associated with the onset of the reproductive state of the shoot apex brought about through changes in the amount of cell extension. A study of the effect of different amounts of low temperature and different day lengths on the relation between inflorescence inception and the production of the longest leaf blade showed that, under some conditions, this relation can be disturbed (*Annals of Botany* NS 23, 217 (1959)).

Belgian Oligocene Foraminifera

THE second of a series of studies on the Belgian Paleogene by a team of micropaleontologists at the University of Utrecht consists of a memoir by D. A. J. Batjes on 'Foraminifera of the Oligocene of Belgium' (Institut Royal des Sciences Naturelles de Belgique Mémoire No 143. Pp 188+13 plates Bruxelles 1958). Hitherto very little was known about them although the Belgian Oligocene includes the type areas of the Tongrian and Rupelian divisions. The samples investigated were collected both from surface outcrops and from borings and mine-shafts, so that essentially the whole Oligocene was covered. Further, some German and Dutch Oligocene and Belgian and German Miocene deposits were examined. Altogether some 140 species (of which two are new) are described, all, with the exception of *Nummulites germanicus* (Bornemann) belonging to the smaller foraminifera. The author considers that some might may be index fossils for the Oligocene or in any event for the Boom Clay and Septaria-clay. One *Cassidulinia carpathina* Hedberg widely distributed in the Tertiary of the Caribbean Antillean area, is described for the first time from Europe. The faunal assemblages have close affinities for much of Oligocene time with those of north western Europe and not with those of areas farther south. Dr Batjes also made detailed observations on the lithology and lateral variation of the deposits in different parts of Belgium. Correlating these with the foraminiferal assemblages, he is led to postulate that parts of the Tongrian and Rupelian deposits are of the same age and that similar relations may exist between the Rupelian and Châtian.

A Reinterpretation of Charnockites

SINCE the publication of Sir Thomas Holland's classic memoir on the charnockite series of peninsular India nearly sixty years ago, similar rocks have been discovered and studied in many parts of the world and various theories of their origin have been put forward without, however, a thorough knowledge of the type area near Madras from which these rocks were first recorded. A detailed re-examination of the rocks of this area has been made by A. P. Subramaniam (*Imperial Science*, 257 331 May 1959). Mineralogical, petrographical, and chemical data are presented which indicate that Holland's 'Charnockite Series' in fact contains members which are genetically unrelated to one another. Charnockite is redefined as a hyporthene quartz feldspar rock with or without garnet characterized by greenish blue feldspars and greyish blue quartz. The term 'charnockite suite' is suggested for a group of related alaskite, charnockites (birkomites), endermites and hypersthene-quartz syenites all of which are partly metamorphic. This series corresponds to the Acid division of Holland's 'Charnockite Series'. The 'Intermediate' division of Holland consists of an assemblage of hybrid rocks

derived by interaction between charnockite magmas and pyroxene granulites of the basement. The "Basic" division of Holland consists principally of pyroxene granulites and interstratified quartzo-felspathic garnetiferous sillimanite gneisses (khondalite), while his "Ultrabasic" division is represented by pyroxenitic schlieren, neither the "Basic" nor "Ultrabasic" divisions being related to the charnockite suite. The charnockite suite of rocks is considered to be of primary igneous origin, and to have been emplaced as thick sheets and lenses in gently folded basement rocks, all the rock units have later suffered intense regional deformation.

Automatic Centrifuge

AN eight-page folder issued recently by Ivan Sorvall, Inc., Norwalk, Connecticut, illustrates and describes the super-speed Servall SS-3 Automatic Centrifuge and the SS-4 Enclosed Centrifuge. Both instruments are table-top models with a marked versatility in accepting any one of five different rotors covering a wide range of batch capacities, speeds and gravitational forces. After the desired operating speed, running time, and rate of deceleration have been pre-set on the SS-3's conveniently angled control panel, the circuit is actuated by the push of a button. A particular advantage of the automatic controls is the accuracy with which a given operation may be repeated and complete uniformity of result maintained. The SS-4 is a manually controlled instrument and the complete control panel is removable for remote operation. This is convenient when work demands operation in cold rooms or fume hoods. Both centrifuges are designed for rapid adaptation to continuous flow operation with the Servall 'Szent-Györgyi and Blum' system, which allows the collection of small amounts of precipitate, in tubes, from gallon quantities of samples.

University News Queen's University of Belfast

THE following appointments to lectureships are announced: Dr C J M Stirling, organic chemistry, Dr J S Pate, botany, Dr B V Jayawant, electrical engineering, N C Mitchel, geography, W D Ryan, light electrical-engineering.

Bristol

THE appointment has been announced of Dr W M Shepherd, reader in the University, to the chair of theoretical mechanics. The following have been appointed to lectureships: P W Bothwell, public health, D R Coles, medicine, D G Osmond, anatomy, R Park, civil engineering, N G Sanerkin, pathology.

London

THE following appointments have been made: Prof J L D'Silva, professor of physiology at London Hospital Medical College, to the Halliburton chair of physiology tenable at King's College, A H J Rams, senior lecturer in the University of Birmingham, to the chair of surgery tenable at Charing Cross Hospital Medical School. The following have been appointed readers: Dr G R Hilson, bacteriology, and Dr D Dexter, morbid anatomy, tenable at St George's Hospital Medical School, J F Smith, morbid anatomy, tenable at University College Hospital Medical School. R E M Thompson, bacteriology, tenable at the Middlesex Hospital

Medical School, Dr P J Grant, engineering science, and Dr B W Martin, applied thermodynamics, tenable at the Imperial College of Science and Technology, E M Rawstron, geography, tenable at Queen Mary College. The title of reader in the University of London has been conferred on T E Hughes, zoology, in respect of his post at Birkbeck College, Dr J Wynn Reeves, psychology, in respect of her post at Bedford College, Dr J H Trounce, therapeutics, in respect of his post at Guy's Hospital Medical School.

University College of North Staffordshire

THE U S Rubber Co has founded a second post graduate research studentship at the College. J Penfold (Nottingham) and J Beard (Southampton) have been appointed to these studentships. The Phillips Petroleum Co of Bartlesville, Oklahoma, has founded a postgraduate research studentship at the College, to which C J Panton (Southampton) has been appointed. All three research students will work with Dr P H Plesch on problems related to cationic polymerization.

Announcements

THE Institute of Physics is to hold a conference on Some Aspects of Magnetism during September 22-24 at Sheffield. Further information may be obtained from the Secretary, Institute of Physics, 47 Belgrave Square, London, S W 1.

AN informal Discussion on Flow Properties of Blood and Other Biological Systems, sponsored jointly by the British Society of Rheology and the Colloid and Biophysics sub-Committee of the Faraday Society, will be held in the Department of Physiology, Oxford, during September 23-24. Further information may be obtained from Dr A L Copley, Medical Research Laboratories, Charing Cross Hospital, Strand, London, W C 2, or from Dr G Stainsby, British Gelatine and Glue Research Association, 2a Dalmeny Avenue, London, N 7.

A SYMPOSIUM on Depression will be held at the University of Cambridge Post-Graduate Medical School during September 22-26. Information may be obtained from the Secretary, Medical School, Tennis Court Road, Cambridge.

THE 250th anniversary of the successful use of coke in ironmaking is to be celebrated by a meeting at the University of Birmingham and at Coalbrookdale, Shropshire, during September 23-25. Further information can be obtained from the Secretary, Iron and Steel Institute, 4 Grosvenor Gardens, London, S W 1.

THE Institute of the Rubber Industry is to hold a conference on Industrial Technical Organization at the Palace Hotel, Southport, during October 9-10. Information can be obtained from the Conference Secretary, Institution of the Rubber Industry, 4 Kensington Palace Gardens, London, W 8.

THE Committee on Geodesy and Geophysics of the Academy of Sciences of the U S S R published in 1957 a short report of 75 pages on the recent work done in the Soviet Union in the field of seismology, seismo-geology, seismological survey, physics of the earth, tectonophysics and the age determination of minerals and rocks. A list of seismological stations, abstracts of some of the papers and bibliographies of others are given.

BRITISH CAST IRON RESEARCH ASSOCIATION

OPEN DAYS

THE British Cast Iron Research Association, Alvechurch, Birmingham, held two open days on May 28 and 29. The first day was arranged for visits by representatives of member firms and the second day for visitors from other research associations, Government laboratories, universities, technical colleges and local schools.

The president of the Association, Mr E. Pleyer, inaugurated a new experimental cupola installation. The cupola is a shaft furnace in which metal, coke and fluxes are charged alternately and air is blown through tuyères up the furnace shaft. This furnace is likely to remain the most important melting unit for cast iron in Britain for very many years. The reactions occurring are highly complex and the unit is capable of innumerable variations in design. This experimental installation is on a full industrial scale, has mechanical charging and an extensive stockyard. Use can be made of cold or hot blast, the latter being achieved by means of a separate oil fired blast heater built with radiation and convection sections. It is expected that air blast temperatures of up to 800° C will be achieved in the experimental work. This range of blast temperature is far higher than that on which there is any industrial experience at present. The furnace will melt up to about six tons an hour and the molten metal produced will be disposed of by means of a pig-casting machine. Interchangeable well and melting zone sections have been provided so that the melting zone profile can be changed and the furnace operated without a refractory lining in the melting zone and with water cooling. The equipment is fully instrumented so that materials and thermal balances can be accurately computed.

Dr J. G. Pearce, formerly director of the Association, opened a new laboratory block to be devoted solely to study of fume and dust in iron foundries and its elimination. This laboratory has a large experimental hall covered by a gantry crane, and is equipped for full scale studies of the various dust extraction and ventilation problems which arise in iron foundries. There is also a dust-estimation laboratory with a comprehensive range of instruments for sampling industrial dusts. Estimation of the free silica content of collected dusts is carried out by X-ray diffraction. Demonstrations were made of various devices developed by the Association for the control of dust produced during the manufacture of iron castings.

In the chemical analytical laboratory the most important display dealt with the application of liquid/liquid solvent extraction and the removal of iron by extraction as chloride, and the acetylacetonate complex was demonstrated. In connection with slag analysis the extraction of heavy metals as diethyl dithiocarbamate complexes is being applied to the determination of aluminium. Another important display in this laboratory dealt with the determination of trace elements. For the determination of aluminium in cast iron the element is separated as the cupferron complex after removal of interfering elements by extraction with diethyldithiocarbamate and chloroform. The separation of cobalt, copper,

lead and bismuth was also illustrated. The determinations were completed by cathode ray polarography or spectrophotometry. The demonstration of special methods of analysis was augmented by the display of a cathode ray polarograph modified by the British Cast Iron Research Association to improve its utility, and a spectrophotometer modified for single beam recording spectrophotometry in the ultra violet region and for use as a high sensitivity recording flame spectrophotometer.

The work of the Association not only covers the material cast iron, but also the material used for the moulds into which the molten metal is cast. These are usually clay bonded silica sands, and the production of castings with good surface finish and free from defects involves consideration of their behaviour when rapidly heated by molten metal. The simulation of this cannot be achieved in the laboratory by heating moulding sand test pieces in normal laboratory furnaces since, because of the low thermal conductivity of the materials, any organic or carbonaceous materials are destroyed before the test pieces are uniformly heated. These carbonaceous materials contribute in an important manner to the properties of moulding sands and are substantially not destroyed before a casting solidifies in a normal mould. To overcome this difficulty a testing machine using dielectric heating has been developed which enables sand test pieces to be rapidly and uniformly heated to any desired temperature. Load/deformation curves can be automatically recorded when the test piece has reached the required temperature. One such unit has now been thoroughly tested and an attempt is being made to build similar equipment using a higher frequency and greater power input for still more rapid heating rates. The technique should be of interest for the testing of other ceramic and refractory materials at high temperatures, particularly where rapid rates of heating are important.

Cast iron is a complex alloy capable of developing a wide range of properties depending upon the manner in which solidification proceeds. The properties of grey cast iron are determined by the dispersion of the graphite phase which originates at a eutectic transformation during solidification. The displays indicated that the solidification of this eutectic had received detailed study in terms of nucleation and growth. It appears that elements which reduce the interfacial energy between graphite and the melt increase the number of nuclei growing at a given degree of undercooling. Sulphur and hydrogen appear to reduce the rate of growth of the eutectic cells. The technique by which the nucleation of the iron is estimated by means of eutectic cell counting was demonstrated and stereophotomicrographs of the graphite skeleton within each eutectic cell were shown to illustrate the growth mechanism. A special cooling-curve furnace used for solidification studies was also displayed. This employed a molybdenum heating element and was constructed so that there was always a constant temperature difference between the surroundings and the sample during solidification and recalescence.

The application of the results of the fundamental work on nucleation to practical problems was well illustrated, particularly in connexion with the soundness of iron castings. Increasing the degree of eutectic nucleation increases the tendency to shrinkage defects, and methods for reducing eutectic nucleation are being tried. The laboratory findings have been well confirmed by industrial trials.

Fundamental work is also proceeding on the interplay of thermal and nucleation effects in the production of chilled castings, and also on the mechanism of solidification of white cast irons in which the eutectic of austenite and iron carbide can appear in various patterns related to the nucleation of the melt and the amount of undercooling before solidification. The detection of eutectic cells in white cast irons has proved difficult and the use of the reflecting polarizing microscope has so far proved to be the most useful tool.

The mechanism of the corrosion attack on cast iron in diesel engine waterways has been studied and the special test rig used was demonstrated. Evidence at present shows this to be caused by the accumulation of acidic oxidation products of the glycol in the coolant, the chief of which is formic acid. The formation of formic acid is probably accelerated by the loss of the copper corrosion inhibitor.

The problem of phosphorus in foundry pig iron was illustrated. To a large extent British iron ores of low phosphorus content are exhausted, and foundry pig irons produced from home ores generally contain more than 1 per cent phosphorus. This element has many harmful effects in cast iron when present in such amounts and the Association has just completed an extensive survey of the possibility of utilizing high phosphorus iron ores for the production of low phosphorus foundry pig iron. It has been possible to demonstrate that by top-blowing with oxygen in a rotary Kaldo converter, the phosphorus of phosphoric pig iron can be substantially eliminated and the iron cheaply recarburized.

Cast iron in steam engineering applications is generally limited to temperatures not exceeding 450° F. The Association has just completed the first part of an investigation showing that this is an unrealistic limitation since almost all cast irons have dimensional stability up to at least 750° F. Creep tests are in progress to provide additional evidence.

Cast iron is not a truly elastic material. When stressed the strain can be shown to involve a recoverable anelastic component and an irrecoverable component. By a study of the stress/strain curve the latter has been shown to involve true plastic deformation and also a mechanism by which the graphite voids are increased in size. The application of triaxial stress systems by means of mild notches is shown to modify the mechanical properties. Typical results obtained in this investigation were demonstrated.

For many years the Association has been studying the influence of the gaseous elements in cast iron, and the practical implications of this work were illustrated. In particular, the influence of aluminium in cast iron in causing the decomposition of water vapour, leading to the solution of hydrogen, was emphasized with many industrial examples.

The Association maintains a Foundry Operations Section to provide the iron-founding industry with an advisory service on productivity and working efficiency. Recently, considerable interest has been displayed in a form of time-lapse ciné photography known as 'Memo-motion' and the equipment used and typical results obtained on foundry operations were demonstrated.

The exhibition material was designed to demonstrate that the work of the Association involved largely applied research undertaken specifically in support of the iron-founding industry, its materials, processes, working conditions and productivity. Many examples were given illustrating how the worker in a more or less fundamental field could receive inspiration and ideas by contact with the day-to-day problems of industry.

H MORROGH

ATOMIC MECHANISMS OF FRACTURE

A CONFERENCE on "The Atomic Mechanisms of Fracture" was held at Swampscott, near Boston, Massachusetts, during April 12-14, organized by the National Academy of Sciences—National Research Council. More than 400 people attended, including about twenty from overseas, and twenty-five papers were presented.

Although the main emphasis was on the properties of metals, there were a number of papers dealing with non-metallic crystals, and non-crystalline solids. In the last category interest centred on dynamic effects. H. Schardin presented some rather precise results on the measurement of crack velocities in glasses of various compositions which showed that, although it is approximately true that the maximum crack velocity is proportional to the speed of longitudinal elastic waves, there are significant discrepancies which appear to be correlated with the chemical constitution of the material. H. Kolsky discussed the similarities in behaviour of plastics and viscous liquids when subjected to tensile-stress pulses of short duration, caused by the stress waves from an explosion. At the other extreme end of the time-

scale, R. J. Charles discussed the dependence upon time of the strength of silicate glasses under static loading. Attributing this to the chemical action of atmospheric water vapour at the tip of a crack, he adduced supporting evidence from the behaviour of crystalline oxides under similar conditions.

In the main field of interest of the conference, it was clear that the complexity of the process of fracture is now agreed. Four types can usefully be distinguished: (1) ductile, (2) brittle, (3) creep, (4) fatigue. It should, however, be emphasized that this is no more than a classification of convenience, each heading probably covers a variety of processes, and when any particular body changes from one piece into two pieces a selection of these processes may have been involved, according to the conditions of the experiment. An extreme case arises when a crystal of a soft metal draws down, in tension, to a chisel edge or a point. The mechanism, doubtfully included under the general heading of fracture, is the flowing of material away from the developing neck, by single or multiple glide processes. It was suggested that the central, fibrous part of the typical

cup and-cone tensile fracture of, say, a copper bar might be essentially similar to this. A paper by C Crussard *et al* emphasized the value of the electron microscope in the study of such fracture surfaces—a value which arises not so much from its high resolving power as from its great depth of focus. Crussard showed that in such a fibrous ductile fracture there is evidence of repeated nucleation of new cracks ahead of the growing tip of the major crack, such nucleation taking place usually at minute inclusions in the metal. The new cracks may then join with the major crack by a process of repeated necking down as just suggested.

R W K Honeycombe and C J Beevers showed that by suitable choice of conditions, such necking can be suppressed, even in single crystals of a face centred cubic material, and that when this is done one obtains a mode of separation which can be more properly called a true ductile fracture, the separation of the two parts taking place along a previously heavily deformed glide plane and being apparently controlled by the resolved shear stress on this plane. On the other hand single crystals of iron tested at low temperatures by N P Allen and B Edmondson, either neck down to 100 per cent reduction of area, as already described, or else cleave along the {100} cleavage plane without obvious prior slip. The choice between the two modes of behaviour is determined by the direction of the tensile stress relative to the crystal axes and the transition is quite sharp.

The topic which received the greatest amount of attention during the conference was the well known ductile-brittle transition in polycrystalline iron which normally takes place rather below room temperature. A paper by G T Hahn, B L Averbach, M Cohen and W S Owen reported an extensive series of observations on the tensile fracture of mild steels, of various compositions and grain sizes, over the temperature range 20–230°K which showed that the phenomena are more complex than had perhaps previously been realized. In particular the authors claim that different processes are important in different ranges of temperature—other things being equal—and that mechanical twinning plays a decisive part at the lowest temperatures.

Microscopic observations of specimens broken, or almost broken, under conditions near those obtaining at the brittle-ductile transition showed the existence of numerous micro-cracks each usually confined to a single grain. The frequency of occurrence of such cracks varied systematically with the conditions of the test and the authors maintain that it is necessary to subdivide the process of fracture in this transition range into: (a) true initiation in which some plastic deformation is probably essential, (b) growth within the original grain, (c) propagation through the rest of the specimen. A useful concept which arises is that the 'effective' value of the surface energy of the newly formed surfaces may be much larger—the authors deduce 10 times larger—for (c) than for (b). This is indeed reasonable in the light of some of the fractographic studies of J R Low, which show very clearly the change of character of a cleavage surface which can take place when the crack passes from one grain into another less favourably oriented for cleavage.

A contribution from N J Petch summarized his own extensive work, relevant to the more metallurgical aspects of the same problem. In addition to the grain size, temperature, and strain rate, which are commonly recognized as important variables, he

discussed also the mechanisms by which the carbon, nitrogen and other elements commonly present in steels affect the various stages of the fracture process and the ways in which their influence can be modified by previous mechanical and thermal treatment. The introductory paper by A H Cottrell also dealt with the brittle-ductile transition at some length, in addition to giving a general survey of the whole subject of the conference. Although some points of controversy remain and although much detailed work remains to be done, it appears that the broad outlines of the explanation of the ductile-brittle transition are becoming settled.

The two main contributions on creep fracture namely on slow fracture at temperatures which are high relative to the melting point came from N J Grant and R C Giffens. The features which distinguish this type of failure from the others are the considerable importance of grain boundary sliding and grain boundary migration, the comparative ease of dislocation climb processes and the possibility of deformation by the migration of point defects under the action of stress. It was made very clear that these four processes can be interrelated in several ways and that they can all be interrelated to any deformation by dislocation glide which may be taking place in the body of the grains. Failure is often, but not always intergranular, and is often, but not always associated with the presence of 'voids' in the grain boundaries. The fracture behaviour was reported to be particularly sensitive to the presence of small amounts of impurity in a nominally pure metal. The paper by Giffens summarized some of the earlier experimental work which is considerable in quantity and not always self-consistent. It is clear that it is likely to be some time before the present confusion approaches anything approximating to a unified body of knowledge although the general lines of the pattern are beginning to emerge.

The problem of fracture during fatigue is perhaps in the least satisfactory state of all. Of the papers presented at the conference most were concerned with the early stages of the process. W A Wood described the interesting results obtained by a taper sectioning method applied to a partially fatigued copper specimen. As with so many other papers on other topics, the impression given by this work is that the mechanism of fracture is more complex than had hitherto been supposed. The emphasis is on the events taking place close to the surface of the solid and leading up to the formation of a true crack. E S Machlin and A J McEvily described experiments on four inorganic crystals which seem to show an interrelation between liability to fatigue fracture and the ability of the crystal to become deformed by cross slip, the possibility of the formation of 'extrusions' from the metal surface also seems to be correlated with both these features. A similar point emerges from a comparison of two papers on copper by W A Backofen and N Thompson respectively, one of which dealt with the effect of crystal orientation on liability to fracture while the other related crystal orientation to extrusions.

Mention must also be made of the contribution by E R Parker on the cleavage fracture in tension of single crystals of magnesium oxide. These observations and similar work by Stokes *et al* mentioned in the course of discussion demonstrate the advantages to be gained by experimenting on ionic rather than metallic crystals and emphasize a point that was made on a number of occasions. This is that on

close examination, no crystal breaks in a truly brittle manner, the fracture is always preceded by some small amount of plastic deformation. This is one of the key points in connecting theories of fracture with current views on the mechanical behaviour of crystalline solids. The other general feature of the

proceedings, already mentioned, was the evident fact that in no circumstances is fracture a simple process. The realization that "when a problem is difficult, it is probably two problems" is perhaps the most important step on the road to a solution.

N. THOMPSON

OXIDATION OF ORGANIC COMPOUNDS

A SYMPOSIUM on the oxidation of organic compounds was held in the Stern Hall at Queen Mary College, University of London, during April 13-14.

In his opening address Mr D. A. C. Dewdney, director of Esso Petroleum Co., Ltd., spoke of the importance of a free exchange of scientific information and the need of still further fundamental research into basic problems, an improving standard of living and higher productivity are largely dependent on the commercial application of original scientific discoveries. In welcoming visitors to the symposium, he referred especially to those from the USSR and Czechoslovakia.

The first part of the scientific discussion was concerned with the course of the oxidation of saturated hydrocarbons by chromic acid in acetic acid containing some sulphuric acid. From the papers and the discussion which developed there was general agreement that the first recognizable stage in the oxidation is hydrogen abstraction from the hydrocarbon, and that the factors which influence the speed of the reaction are mainly steric and configurational. The same factors also determine the rate of oxidation by chromium trioxide in anhydrous media.

Dr J. Roček (Institute of Chemistry, Czechoslovak Academy of Science, Prague) reported that *n*-paraffins are oxidized at a rate directly proportional to the number of methylene groups, the rate constant for any individual member being $k_n = k_{CH_2}(n-2)$, where n is the number of carbon atoms and k_{CH_2} the rate constant for the oxidation of a single methylene group. The relative rates of oxidation of the methyl, methylene, and methine groups in open chain hydrocarbons have been found to be 0.015:1:32-77. Measurements of the rate of oxidation of *cycloalkanes* disclosed some interesting anomalies.

The oxidation-rate of the tertiary CH-group is found to vary somewhat with the bulk and structure of the neighbouring alkyl groups, these variations are due mainly to polar factors and are similar to changes in rates of solvolysis of the corresponding tertiary chlorides. Only in special cases has steric retardation been found, steric acceleration does not play any detectable part in the acyclic series. It is concluded that the rate-determining step is the formation of a carbonium ion by way of a hydride ion transfer from the hydrocarbon molecule to an oxygen atom of the oxidizing agent.

Prof K. B. Wiberg (University of Washington) from a study of the rate of oxidation of diphenylmethane and of its nuclear substituted derivatives in 95 per cent acetic acid concluded that the oxidation proceeds by initial removal of a hydrogen atom to give a benzhydryl radical which is then oxidized directly to benzophenone. In support of such a mechanism, oxidation of optically active 3-methylhexane gives an optically active tertiary alcohol, a result which seems to exclude the initial formation

of a carbonium ion. The formation of camphenilamic acid by the oxidation of isocamphane is also cited in support of that view. Further evidence of an indirect nature is derived from a study of the action of chromyl chloride on propylbenzene- β - d_2 , benzyl methyl ketone is among the products, and it was found to have one deuterium atom in the α -position, indicating a deuterium shift during the reaction.

The oxidation of tertiary paraffins by chromic acid in presence of sulphuric acid is known to lead to tertiary alcohols, and the course of the reaction can be interpreted in terms of dehydration of the alcohol to olefin. In a study of the oxidation by Dr W. J. Hickinbottom (Queen Mary College, London) the conditions were selected so that tertiary alcohols could not be formed, by using chromium trioxide in acetic anhydride. Under these conditions, paraffins gave products which were qualitatively identical with those from the corresponding olefins in presence of weak acids. Further, some of the paraffins gave unsaturated products. From these results and from quantitative measurements of the rates of oxidation it was concluded that tertiary paraffins are attacked preferentially at the tertiary carbon atom with the subsequent formation of an olefin.

A possible key to the oxidation of paraffins by chromic acid may lie in the behaviour of the alcohols which may be derived from them by oxidation. Our knowledge of the course of the oxidation of alcohols is based on the work of Prof F. H. Westheimer (Harvard University). In continuation of this work, he described, with Y. E. Chang, a study of the oxidation of pinacol and its monomethyl ether. A feature of the pinacol oxidation is that it proceeds 2.7 times as fast in deuterium oxide as in water. This was interpreted to mean that the hydroxyl bond is not cleaved in the rate controlling step of the oxidation. The relative merits of an ester mechanism and hydride abstraction were discussed and many useful ideas exchanged.

Dr W. A. Waters (Oxford) reviewed the relationship between vanadate and permanganate oxidations. The role of trivalent manganese and of organic free radical intermediates in permanganate oxidations was reviewed. Features diagnostic of one-electron oxidations were brought to notice. It was stressed that lack of diagnostic evidence need afford no grounds for the rejection of a reaction mechanism.

Dr J. W. Ladbury (ICI, Ltd., Plastics Division, Welwyn Garden City) and Dr C. F. Cullis (Imperial College of Science and Technology, London) discussed the oxidation of inorganic and organic compounds by permanganate. The development of reaction rate with time depends on the nature of the compound undergoing oxidation. The observed types of behaviour fall, broadly speaking, into four categories according to the shape of the reaction-time curves. Thus there may be (1) a continuous decrease in rate with time, usually not strictly according to a

second-order knot law, (2) an initial autocatalytic development of reaction rate followed eventually by a decrease due to consumption of reactants (3) an initial high rate of reaction which rapidly decreases almost to zero and is then followed by an autocatalytic reaction of type (2) (4) an initial high rate followed by a linear reaction - time curve. These various kinds of behaviour were discussed and reasons proposed for the characteristic differences observed according to the nature of the substrates. In the discussion on this Prof N M Emanuel (Moscow) directed attention to the resemblance between type (3) and the oxidation behaviour he had observed using oxygen.

Dr S Littler and Dr W A Winters (Oxford) reported that pentavalent vanadium becomes an oxidizer in acid solution, the active agents being cations, for example, VO_2^+ , $\text{V}(\text{OH})_2^{2+}$, depending on the acidity which reduces only to the oxidation level of quadrivalent vanadium with organic compounds. Kinetic studies were reported of some glycol isomers and of the oxidation of *cyclohexanol*. In the latter case an initial rapid esterification seems to be involved though the rate-determining stage involves C-H bond fission. Isotope effects in *cyclohexanol* depending on the oxidizing ion were discussed and a cyclic mechanism proposed.

The oxidation of saturated hydrocarbons in the liquid phase by air is now a matter of both industrial and theoretical importance. Prof A N Bashkurov (Moscow) described his work on the oxidation of the higher paraffins. In this he described a very important development, namely, that the oxidation can be arrested at a predetermined stage. By using barium salt and selecting suitable conditions—a temperature of 105–170°C and a nitrogen-oxygen mixture containing 3–4.5 per cent of oxygen—the higher paraffins can be converted into the corresponding alcohols in 70 per cent yield. There is practically no degradation of the hydrocarbon molecule and all the possible secondary alcohols are formed.

Prof N M Emanuel (Moscow) discussed a number of interesting aspects of slow branched-chain oxidation reactions of hydrocarbons and reference was particularly made to the capacity for auto-acceleration and self propagation and the control of these reactions by homogeneous catalysts. Some of the ideas

developed in this paper were shown to have application in biological processes such as retardation and suppression of the growth of malignant tumours in animals.

Prof H B Henbest (Queen's University, Belfast) reported that trialkylamines are readily oxidized by a large variety of reagents, the initial products being usually N-oxides, enamines or carbinolamines. Depending on its structure and the reaction conditions a compound of the last type may be oxidized further to an amide or may cleave to a mixture of a secondary amine and a carbonyl compound. Analogous compounds may be formed in the oxidation of dialkyl anilines but in this series additional products are possible if nuclear positions become involved in the reaction.

A general survey of the field was presented followed by a more detailed discussion of some of the reactions of trialkylamines and dialkylanilines with N-bromo succinimide, ceric salts, p-quinones, di-tert-butyl peroxide, and benzoyl peroxide. The results with dialkylanilines suggest that the three primary oxidation processes of electron removal, hydrogen atom removal, and hydride ion removal can all occur, the choice for any particular amine being mainly dependent on the type of oxidizing agent used.

Some known features of oxidations by persulphates were summarized by Dr R G R Bacon (Queen's University Belfast) and new data presented. Persulphates may be employed (a) as aqueous solutions, undergoing thermal or photo induced decomposition; (b) in strongly acidic solutions; (c) in alkaline solutions; (d) in redox systems, where persulphate acts in conjunction with, for example an oxidizable metal ion. The use of persulphate in redox systems was discussed with emphasis on the value of silver ion as the redox partner. Applications of this method to oxidations of alkylbenzenes, phenols, alcohols, carboxylic acids, and amines, were described.

In summing up the proceedings of the symposium, it can be said that its success as a scientific meeting depended very largely on the free and uninhibited exchange of ideas and the discussion of current and unpublished work now in progress.

R F GARWOOD

GAS CHROMATOGRAPHY

THE Gas Chromatography Discussion Group associated with the Hydrocarbon Research Group of the Institute of Petroleum has now completed its reorganization following an inaugural general meeting last autumn held at University College London, on September 23, 1958 and the first annual general meeting at the Imperial College of Science and Technology, London on April 10, 1959. Both meetings were held in conjunction with an informal symposium and were attended by more than two hundred participants.

The success of the new organization may be judged from the total enrolled membership, which is now about 220 of which some fifty are from the Continent or the United States. The Group has now organized four one day informal symposia in Britain and the second formal symposium in Amsterdam in the spring of 1958 which was attended by nearly

five hundred participants from twenty one different countries. In addition it has published two papers and arranged for the manufacture and sale in the United Kingdom of specially prepared stationary phases and supports in an endeavour to standardize experimental procedures for determining and methods of presenting gas chromatographic data. Arrangements are being completed for the collection and distribution of the latter to members together with abstracts of papers on the technique from more than sixty journals. The future programme tentatively includes another informal symposium to be held at Bristol in the autumn of 1959 and the third formal symposium in Edinburgh during 1960. The outstanding contributions of Dr A J P Martin both in originating gas-liquid chromatography and in many important later developments have been recognized by the Group by bestowing on him honorary life membership.

The technical part of the meeting at University College, London, on September 23, 1958, was introduced by Prof E D Hughes, who gave a short welcoming address commenting on the rapid growth of the Group. Dr D Ambrose, the local organizer, then presented proposals on behalf of the Group for the determination of retention volumes under standard conditions. Various practical points about the experimental procedures were discussed, including temperature control and the life of columns.

Dr G A P Tuey described the work done in his laboratories in preparation for the sale of standardized materials for use as stationary phases. Extensive tests had been made of volatility in an apparatus which simulates conditions in the chromatographic column but allows a gravimetric determination of the loss at a particular temperature. The rate of loss with time was determined and a final specification includes a figure for initial loss, the steady rate of loss and relative and specific retention data.

The comparison of detectors for gas chromatography was the subject of a paper presented by Dr I G McWilliam. Detectors were discussed in terms of sensitivity, response time, relationship of detector output to molecular parameters and ease of construction and operation. The sensitivity is best stated in terms of gas concentration, and the unit gm/ml of carrier gas was advocated. Base-line noise (μV) and drift ($\mu\text{V/hr}$) should also be stated. The response time must be small enough for negligible distortion of the true peak shape to occur. If the relationship between detector output and some molecular parameter is known, quantitative analysis without calibration is facilitated. Although all these factors must be considered in selecting a detector, the final choice frequently depends upon the ease of construction and operation. Of those in use, Dr McWilliam considers the single-jet flame ionization detector the simplest.

Dr K R Garrett presented a report on a programme of co-operative analysis of hydrocarbon gases organized by the Institute of Petroleum. Cylinders containing sales butane and a cracked C_4 -mixture have been circulated among participating laboratories, where they have been analysed using a range of techniques. Preliminary results indicate the importance of standardization of methods of taking samples from the cylinders and enable some assessment to be made of the reproducibility of possible standard procedures.

An interesting study of alumina as a packing was described by Mr C G Scott. Several methods of achieving different levels of adsorption activity had been tried, but the most promising seemed to be the addition of small quantities of water and silicone oil. With optimum proportions it was possible to maintain the ability of the adsorbent to separate hydrogen and methane but with much reduced retention volumes for the higher hydrocarbons. An analysis of a gas mixture containing hydrogen, C_1 , C_2 , C_3 , C_4 and C_5 -hydrocarbons was therefore possible in a single run at constant temperature.

Prof R M Barrer welcomed the Group to the Imperial College of Science and Technology, London, on April 10, 1959, congratulating it on the excellence of the meetings it organized and the vigour and enterprise shown by such a comparatively new organization. The local organization of this meeting was carried out by Dr G J Minkoff. The first paper, presented by Dr A Goldup, was concerned with the potentialities of the new coated capillary columns in

the petroleum industry. He described a compact practical apparatus with which capillary columns had been operated at temperatures up to 250°C . Column efficiencies in excess of 100,000 theoretical plates had been obtained with metal tubes ten thousandths of an inch in diameter and 250 ft long coated with squalane or 'Apiezon' grease. A novel sample introduction device was described in which the very small samples required for the column were obtained by a dynamic division of the carrier gas at the column head. The use of these high-efficiency columns in the analysis of various petroleum products and in geochemical prospecting was illustrated. Mr B H F Whyman, another of the authors of this paper, in a prepared contribution to the discussion, described a simple apparatus for drawing long lengths of coiled glass capillary, which show certain advantages over metal capillary.

Mr R P W Scott then described the use of fine nylon tubes (0.01 in, 0.02 in and 0.1 in in diameter) as capillary columns. Simple coating procedures were used, the transparency of the nylon being helpful in adjusting the rate of flow of the solution of the stationary phase through the tube. A column 1,000 ft in length of 0.02 in diameter coated with dinonyl phthalate gave a maximum of 750,000 plates, but the efficiency tended to fall off rapidly with increasing retention time to about 250,000 plates. Operating temperatures were limited to about 100°C with present tubing, but 180°C seemed feasible with other polymers. A very active discussion took place following these two papers and it is obvious that there is much interest in these new capillary columns, which M J E Golay described for the first time in the autumn of 1957.

A new detector employing changes of dielectric constant developed primarily for preparative-scale gas chromatography was described by Mr D W Turner. For this application, where high sensitivity is not so important as for analytical work, the detector has the advantages of being largely independent of flow-rate, non-destructive and reasonably robust. It employs a novel circuit which is very sensitive to the minute capacity changes produced in the detector cell, and with slight modifications is easily used with solutions such as are encountered in liquid chromatography.

Mr V Willis presented a paper on the application of gas chromatography to process stream monitoring, where an instrument is required automatically to sample and analyse a gas or liquid stream over long periods. A column-life of two years is aimed at, but is difficult to attain with many stationary phases. Although a useful survey of requirements was given, unfortunately few constructional details were available.

Finally, in the last paper Dr S H Langer discussed his work on improvement in stationary phase selectivity. He exemplified this with his results using tetrahalophthalate esters for the separation of the aromatic hydrocarbons. These esters had been selected in an endeavour to exploit the complex formation known to exist between tetrachlorophthalic anhydride and condensed aromatic hydrocarbons. Effective separations of the lower aromatic hydrocarbons had been obtained and separation factors and activity coefficients were compared with other stationary phases. It seems likely that the electron-deficient tetrahalo-substituted ring interacts with the aromatic compounds by a charge-transfer mechanism.

RADIATION SAFETY AND HEALTH PHYSICS

By J W LUCAS

THE Windscale reactor incident of October 1957 involving the release of radioactive fission products into the atmosphere¹, undoubtedly served to focus the attention of the general public on to the hazards of ionizing radiation and to the increasing risks of exposure. Interest has also been aroused by the publication of reports by the Ministry of Health, Medical Research Council² and the UN Scientific Committee³. The rapid expansion of the nuclear power programme coupled with the increasing employment of sources of ionizing radiation in industry, medicine and research institutions, and also nuclear weapon testing demands an increasing vigilance and knowledge of the risks and safety precautions on the part of many people. The U.K. Atomic Energy Authority has an excellent record of safety both with respect to its own staff and to the general public in the vicinity of its establishments and has also exercised a rigorous control over the discharge of waste radioactive products into the environment⁴. The Fleck Committee set up to inquire into the organization for control of health and safety⁵ nevertheless recognized the need for a rapid expansion of health physics and safety staffs in the Authority, and recommended that the Research Establishment at Harwell should set up a national training centre for health physics and nuclear safety staff to cater for persons both inside and outside the Authority.

A number of short courses on "Radiological Protection" have already been held at the Isotope School Harwell, but it was felt that there was scope for a college of technology to undertake similar work. An approach was therefore made to the United Kingdom Atomic Energy Authority, Industrial Group, at Risley, in the spring of 1958 with the view of introducing courses in the Liverpool College of Technology later in the year. A scheme was prepared in conjunction with the Authority and this article provides a brief interim report based on experience of three courses which have been run in late 1958 and early 1959.

Each course is of a fortnight's duration. The available places on the three courses have been taken up by representatives of the U.K. Atomic Energy

Authority, public health departments, factory inspectorate, local industry, insurance and education, members attending include medical officers, physicists, engineers, insurance accident surveyors, chemists, public health inspectors and safety officers.

The aim of the courses has been to provide an introduction to and a general survey of, the problems of radiological protection against all forms of ionizing radiation. The very specialized problems of reactor safety and the processing of nuclear fuel elements have not been dealt with specifically, except in so far as environmental effects may be involved. Special attention in both lectures and practical work is however given to subjects such as the comparative properties of radiations, the sources of radiation including background and fall-out, the effects of radiation on plants, animals and man, contamination and decontamination, waste disposal, health physics instrumentation and monitoring, procedures for absorption of radiation and shielding. Table I summarizes the lecture and practical topics which have been covered on the early courses; the programme is rounded off by visits to local institutions and works by the exhibition of films, and by discussions.

The programme of practical work has been devised to provide a series of short term experiments underlining the basic problems of a comprehensive protection service. Some aspects of the practical work and the results which have been obtained have already proved of considerable interest and are briefly described. It is hoped to publish the detailed observations at a later date.

The experiments in radiobiology have been singularly successful in demonstrating the fate of various radioisotopes when brought into contact with biological organisms to be found in a natural environment. The techniques have been previously described by D G Pickering and myself⁶. The experiments with blanket weed (*Microspora*) have demonstrated conclusively the ability of the algae to concentrate many isotopes from their environment and have particularly served to emphasize the importance of properly planned disposal procedures. A safe procedure for radioactive liquid waste is afterwards demonstrated to members of the course.

Table I. SYLLABUS OF LECTURES AND PRACTICAL WORK

| Lectures | | | Practical | |
|--|--|-------------|---|--------------------|
| Section | Topics | No of hours | Subject | No of hours |
| Radiation and its sources | Comparative properties, units and calculations of dose; background and fall-out; nuclear reactors; particle accelerators | 6 | X-ray equipment and sealed sources. Techniques with open isotopes—counting and identification | 1 |
| Measurement and detection of radiation | Principles of measurement types of counter and I.P. instruments | 6 | Calibration and operation of H.I. instruments. Dosage calculations | 3 |
| Interaction of radiation and matter | Radiation chemistry; radio-biology—genetics; metabolic processes | 6 | Radiobiology | - |
| Radiological protection | I.C.P.L.s and M.I.C.s: control of internal and external radiation in laboratories and plants; medical care; waste disposal; legal requirements; industrial practice; X-ray units | 10 | Contamination—prevention and removal Waste disposal Shielding Radiation monitoring Air sampling | 4 3 10 10 |

Lectures have been presented by members of the Health and Safety Branch of the U.K. Atomic Energy Authority Industrial Group, Factory Inspectorate and the Universities of Leeds and Liverpool in addition to College staff.

The technical part of the meeting at University College, London, on September 23, 1958, was introduced by Prof E D Hughes, who gave a short welcoming address commenting on the rapid growth of the Group. Dr D Ambrose, the local organizer, then presented proposals on behalf of the Group for the determination of retention volumes under standard conditions. Various practical points about the experimental procedures were discussed, including temperature control and the life of columns.

Dr G A P Tvey described the work done in his laboratories in preparation for the sale of standardized materials for use as stationary phases. Extensive tests had been made of volatility in an apparatus which simulates conditions in the chromatographic column but allows a gravimetric determination of the loss at a particular temperature. The rate of loss with time was determined and a final specification includes a figure for initial loss, the steady rate of loss and relative and specific retention data.

The comparison of detectors for gas chromatography was the subject of a paper presented by Dr I G McWilliam. Detectors were discussed in terms of sensitivity, response time, relationship of detector output to molecular parameters and ease of construction and operation. The sensitivity is best stated in terms of gas concentration, and the unit $\mu\text{g}/\text{ml}$ of carrier gas was advocated. Base-line noise (μV) and drift ($\mu\text{V}/\text{hr}$) should also be stated. The response time must be small enough for negligible distortion of the true peak shape to occur. If the relationship between detector output and some molecular parameter is known, quantitative analysis without calibration is facilitated. Although all these factors must be considered in selecting a detector, the final choice frequently depends upon the ease of construction and operation. Of those in use, Dr McWilliam considers the single-jet flame ionization detector the simplest.

Dr K R Garrett presented a report on a programme of co-operative analysis of hydrocarbon gases organized by the Institute of Petroleum. Cylinders containing sales butane and a cracked C_4 -mixture have been circulated among participating laboratories, where they have been analysed using a range of techniques. Preliminary results indicate the importance of standardization of methods of taking samples from the cylinders and enable some assessment to be made of the reproducibility of possible standard procedures.

An interesting study of alumina as a packing was described by Mr C G Scott. Several methods of achieving different levels of adsorption activity had been tried, but the most promising seemed to be the addition of small quantities of water and silicone oil. With optimum proportions it was possible to maintain the ability of the adsorbent to separate hydrogen and methane but with much reduced retention volumes for the higher hydrocarbons. An analysis of a gas mixture containing hydrogen, C_1 -, C_2 -, C_3 -, C_4 - and C_5 -hydrocarbons was therefore possible in a single run at constant temperature.

Prof R M Barrer welcomed the Group to the Imperial College of Science and Technology, London, on April 10, 1959, congratulating it on the excellence of the meetings it organized and the vigour and enterprise shown by such a comparatively new organization. The local organization of this meeting was carried out by Dr G J Minkoff. The first paper, presented by Dr A Goldup, was concerned with the potentialities of the new coated capillary columns in

the petroleum industry. He described a compact practical apparatus with which capillary columns had been operated at temperatures up to 250°C . Column efficiencies in excess of 100,000 theoretical plates had been obtained with metal tubes ten thousandths of an inch in diameter and 250 ft long coated with squalane or 'Apiezon' grease. A novel sample introduction device was described in which the very small samples required for the column were obtained by a dynamic division of the carrier gas at the column head. The use of these high-efficiency columns in the analysis of various petroleum products and in geochemical prospecting was illustrated. Mr B H F Whyman, another of the authors of this paper, in a prepared contribution to the discussion, described a simple apparatus for drawing long lengths of coiled glass capillary, which show certain advantages over metal capillary.

Mr R P W Scott then described the use of fine nylon tubes (0.01 in, 0.02 in and 0.1 in in diameter) as capillary columns. Simple coating procedures were used, the transparency of the nylon being helpful in adjusting the rate of flow of the solution of the stationary phase through the tube. A column 1,000 ft in length of 0.02 in diameter coated with dinonyl phthalate gave a maximum of 750,000 plates, but the efficiency tended to fall off rapidly with increasing retention time to about 250,000 plates. Operating temperatures were limited to about 100°C with present tubing, but 180°C seemed feasible with other polymers. A very active discussion took place following these two papers and it is obvious that there is much interest in these new capillary columns, which M J E Golay described for the first time in the autumn of 1957.

A new detector employing changes of dielectric constant developed primarily for preparative scale gas chromatography was described by Mr D W Turner. For this application, where high sensitivity is not so important as for analytical work, the detector has the advantages of being largely independent of flow-rate, non-destructive and reasonably robust. It employs a novel circuit which is very sensitive to the minute capacity changes produced in the detector cell, and with slight modifications is easily used with solutions such as are encountered in liquid chromatography.

Mr V Willis presented a paper on the application of gas chromatography to process stream monitoring, where an instrument is required automatically to sample and analyse a gas or liquid stream over long periods. A column-life of two years is aimed at, but is difficult to attain with many stationary phases. Although a useful survey of requirements was given, unfortunately few constructional details were available.

Finally, in the last paper Dr S H Langer discussed his work on improvement in stationary phase selectivity. He exemplified this with his results using tetrahalophthalate esters for the separation of the aromatic hydrocarbons. These esters had been selected in an endeavour to exploit the complex formation known to exist between tetrachlorophthalic anhydride and condensed aromatic hydrocarbons. Effective separations of the lower aromatic hydrocarbons had been obtained and separation factors and activity coefficients were compared with other stationary phases. It seems likely that the electron deficient tetrahalo-substituted ring interacts with the aromatic compounds by a charge-transfer mechanism.

D H DESTY

titles, a card index is issued free to members and can be bought by others. It consists mainly of films on pure and applied science, but no subject is ignored which is within the scope of a university. Medical films are also listed, but the Committee tries to avoid duplication of the work of the Film Committee of the British Medical Association and related organizations. Catalogues are, as a rule, easily accessible in university reference libraries, and many member institutions have as many as three copies in constant use. Index cards are 2d each to non-members (minimum 5s) and a revised list was published early in 1957. The Council also publishes the *University Film Journal* about three times a year which contains relevant articles of interest to

staff and students in universities, important reprints and as much news material from home and overseas as possible. At the time of writing, inquiries are being circulated throughout all member universities on the quality and kind of film needed by lecturers and professors, and what special film equipment is being held and would be available to colleagues.

The Council has successfully sponsored special conferences on the use of films in such diverse fields as modern languages (at the Institut français), arts subjects (at the Institute of Education, London), chemical engineering (at Birmingham), psychology (at University College, London). It has also in the past, assisted in the selection of films for the annual British Association meetings. J. HORNE

UNIVERSITIES AND ADULT EDUCATION IN BRITAIN

THE total number of courses conducted in Britain by university extra mural departments during 1957-58 were rather fewer than during 1956-57, but still above the figure for 1955-56. Although this may give cause for modest satisfaction, the slight decline which took place was not evenly spread over the whole of the work but affected with disproportionate severity tutorial classes and residential courses, two branches of work which universities have traditionally cherished*. Since the beginning of the current decade the tendency has been for the number of tutorial classes to decline, but the sharp drop during 1957-58 is without recent precedent.

There are signs that the policy of financial limitation initiated a few years ago is now affecting extramural work particularly in the type of course provided. In such work it is difficult to stand still; an attempt to curb developments inherent in the work is apt to lead to retrogression. Many extra-

mural departments were just able to hold their own, or reported small increases in the number of classes (usually shorter classes) in spite of grant problems.

At Glasgow it was reported that during the past year some of the emergency cuts which had to be made, such as the reduction of the library grant, are likely to have a harmful effect on the quality of the work unless they can soon be restored. Nottingham had to reject ten requests from classes because of shortage of funds. At Oxford also there were financial problems. "The University Chest found itself forced to cut its grant for extra mural work, with the result that the adult scholarship scheme was suspended and the number of classes fell more sharply than at any other university." The Delegacy for Extra Mural Studies stated, in a memorandum submitted to the Hebdomadal Council, its firm belief in the value and importance of extra mural studies, and "its regret that the work must be contracted at a time when the need for it had become even more urgent."

THE CENTRAL AGRICULTURAL RESEARCH STATION, CARAPICAIMA, TRINIDAD

By DR. A. J. VLITOS

Director

THE new Central Agricultural Research Station located at Carapichaima, Trinidad, is an institution intended to foster fundamental and applied research relative to sugar cane. Supported by private funds (Caroni Ltd. and Ste. Madeleine Sugar Co., Ltd.) the new Research Station is concerned with the agronomy, physiology, pathology, entomology, and biochemistry of sugar cane with the ultimate aim of applying in the field new information which may be forthcoming from the basic investigations.

The main section of the Station houses the physiology, pathology, entomology, and biochemistry units in an air conditioned laboratory, fully equipped with the facilities required to carry out the research programmes. Adjacent to main laboratories are dark rooms and a temperature-controlled light room suitable for the growth of plants under controlled environmental conditions. A library, containing the pertinent scientific journals is located in the east wing of the main building.

An agronomic programme, more applied in nature, will complement the fundamental studies in physiology. A major effort is being directed towards the control of froghopper (*Aeneolamia varia saccharina*) and the other major insect pests of cane in Trinidad. Chemical weed control, as well as new methods of cultivation, are also under investigation. Physiological and biochemical studies are concerned with the auxin relations in the developing cane seedling, from seed to flowering. In addition to the auxin studies, several investigations on mineral nutrition and photosynthetic efficiency will round out the physiology programme. The pathology programme is devoted to a thorough study of the rhizosphere of sugar cane, including a taxonomic investigation of the microflora and microfauna residing in the immediate vicinity of the root system as well as an analysis of the interrelationships between the secretions of the root system and the microbial population.

THE LISTER INSTITUTE

THE report of the Governing Body on the work of the Lister Institute for 1959 describes a wide range of investigations*. In the field of microbiology the Guinness-Lister Unit continues its exploitation of the genetics of *Salmonella* bacilli, mainly in terms of the biochemistry and genetic control of the synthesis and function of flagella, using the bacteriophages that infect these bacilli to transduce genetic material from one kind of bacillus to another. The bacteriophage transduction technique has been extended to staphylococci. The other purely biological study concerns the cytology of certain free-living, flagellated protozoa.

Studies by Institute staff into the immunology and pathology of infective diseases are concerned with infections by viruses, pleuropneumonia-like organisms, bacteria and protozoa.

The isolation of the viruses of trachoma and of inclusion blennorrhoea has opened up a large field of study, both in Gambian laboratories of the Medical Research Council's Trachoma Unit, where the epidemiology of trachoma is being studied, and in the Council's Unit in the Department of Virology. The ready infection of the baboon's conjunctiva with the virus of inclusion blennorrhoea provides an experimental model in which to study the practicability of prophylactic immunization in the related infection by trachoma virus. In the Smallpox Vaccine Department, there is continued progress towards making vaccine from vaccinia virus grown in tissue culture, as an alternative to virus harvested from the skin of infected sheep.

The investigation of a bacterial urethritis in man established a genital type of pleuropneumonia-like organism as a possible cause. In man, however, the incidence of antibodies to pleuropneumonia-like organisms was not correlated with the presence of the organisms in the genitalia, so a detailed study of the relation of the pleuropneumonia-like organism antibody response to infections by the organism is being made, in the first place in experimental infections of the rat.

The immunological study of bacterial infections shows further progress in identifying the two antigens of the whooping cough bacillus responsible for prophylactic immunization and the exclusion of the histamine-sensitizing antigen as being immunogenic as well as a search for immunizing somatic antigens in the diphtheria bacillus and an analysis of the iota toxin of *Clostridium welchii*, a bacillus that may play an aetiological part in infective haemorrhagic fever. The study continues of the biologically active substances formed when diphtheria anti-toxins are refined by proteolysis, and of the actual enzymic process of refinement.

With pathogenic protozoa, the antigenic analysis of *Trichomonas* species continues and a new field has been entered in an attack on the immunology of trypanosomiasis. Soluble trypanosome antigens, formed during experimental trypanosomiasis of the rat, are under investigation and the *in vitro* culture of trypanosomes is being attempted to provide bulk material for antigenic analysis of these protozoa.

The refined serological methods devised to identify the animal source of food for blood-sucking insects continues to provide valuable facts about the feeding habits of tsetse flies and mosquitoes in regions where these insects are vectors, or possible vectors, of disease.

Work on the relation of early tissue reactions to defence against microbial infection continues. The tissue response to various kinds of injury, including infection, was explored to determine the role, if any, of the serum proteases which increase capillary permeability. The investigation of early non-specific resistance to bacteria was extended to infections by tubercle bacilli.

The biochemical researches mainly concern three kinds of substances—the blood group substances, the cellular phospholipids and starches.

During the year the problem of homogeneity of the blood-group specific substances isolated from secretions and digests of tissue has received careful attention and new methods of analysis have revealed that in the natural secretions blood specificity is associated with at least two types of mucopolysaccharide molecule. Progress was made in the separation and purification of enzymes which destroy the serological activity of the blood-group substances, and the chemical changes associated with loss of activity were investigated.

The phospholipid study is at present directed to defining the constitution of tissue phospholipids which, although ill-described, are known to be metabolically active. The structure of one of these, cardiolipin, has been elucidated and work is proceeding on the fatty constituents of the plasmalogens and the polyglycerophosphates.

The plant enzymes established as responsible for the synthesis and degradation of starch have been characterized in terms of their individual actions on starch. These enzymes were studied particularly in respect of their combined actions in systems thought likely to reproduce the conditions in which starch is synthesized *in vivo*, and of their separate actions on chemically modified substrates, designed to yield information on the specificity of the enzymes.

On human plasma proteins, the Institute's work is concerned with the isolation, refinement, characterization, assay and in some cases clinical trial of the various biologically active proteins of human plasma.

The difficulties of specifying the potency of preparations of anti-haemophilic globulins for use in haemophiliacs has necessitated a re-examination of modes of assay; clinical studies of the efficacy of the human preparation are in progress. The therapeutic value of γ -globulin in the treatment of hypogammaglobulinaemia is the subject of another clinical study. Studies of the isolation of active proteins include that of plasmin for clinical use and the conditions of its activation from the precursor plasminogen during the fractionation of serum as well as that of oxidase caeruloplasmin. Pathological studies include investigations of the so-called 'macroglobulins' that occur in hyperglobulinaemic sera and of the proteins that appear in the urine of man and animals poisoned by heavy metals.

A THEORY OF THE ABRASION OF SOLIDS SUCH AS METALS

By J GODDARD, H J HARKER and H WILMAN

Applied Physical Chemistry of Surfaces Laboratory Chemical Engineering Department,
Imperial College of Science and Technology London S W 7

ABRASIVE wear is particularly important in machine bearings and gears¹ as well as in the mechanical surfacing of metals. Nevertheless, hitherto there has been no adequate theory to account quantitatively for the observed friction and wear of metals during abrasion. In particular, no simple relation between wear and friction has been observed. We have now observed such a clear and interpretable relation (see equation 1, below) and this has led us to develop the theory outlined below, which accounts well for the abrasion phenomena in the case of metals and similar solids, where the deformation is mainly plastic.

As the hard abrasive surface we have used emery papers having a mean particle diameter of 5, 10, 15, 35, 45, 70, 100 and 150 microns (grades 0000 to 3) since these represent at least approximately defined degrees of roughness down to a fineness not easily obtained by machining. The metals (copper, silver, platinum, aluminium, iron, molybdenum, tungsten) were blocks having about 3 cm² nominal bearing area and these were slid at about 5 cm/sec under loads (W) of up to 2 kgm on these emery papers. Practically identical results were obtained with the emery either dry or wet with propyl alcohol, except in the case of aluminium which showed negligible pick up of emery when wet, but extensive pick up and abnormally high friction when dry.

Figs 1 (curves a and b) and 2 show for example in the case of copper and tungsten the typical variation of the coefficient of friction, μ , and the wear per unit distance M respectively, with the mean diameter D of the emery particles.

Spurr and Nowcomb² made similar experiments but with loading via a lever arm on which the specimen (3/16 in diameter rod but probably about 0.1 cm diameter of bearing surface) was fixed and under which the emery paper passed on a trolley. Instead of the form of variation of μ with D shown in Fig 1 (curves a and b), with its fall at low D to a value close to that for the metal sliding on a similar metal surface they concluded μ increased linearly with D the rise (~ 0.1) being due to the ploughing component³ μ_p , which was assumed to be zero at $D = 0$, and proportional to D . In our more general conditions we have used specimens of considerable length (~ 2 cm for curves a and b in Fig 1) in the sliding direction. We conclude that on the finer grades of emery (D small), only in a limited front region of the specimen bearing face are there effective contacts and indentations of the emery particles into the metal. This region is estimated to be only ~ 0.1 cm for 0000 emery, but it must increase (roughly proportionally) with increasing diameter of the abrasive particles. In the remaining rear part of the face, the metal is mainly in contact with metal which has been worn away from the front specimen region and is almost completely clogging the emery in the operative bearing area. In agreement with our quantitative theoretical estimations, we find the variation of μ with D is much less (approximately that found by Spurr and Nowcomb²) when a shorter

Fig 1 μ for copper (—●— 2 cm specimen length —○— 0.18 cm specimen length) and tungsten (—x— 2 cm specimen length) sliding on various grades of emery paper

copper specimen (0.18 cm) is used as in curve a of Fig 1.

We find a corresponding form of variation of M with D (Fig 2), also not previously described. The data of Figs 1 and 2 also give Fig 3 indicating an effectively linear variation of M with μ . Since M is also proportional to the load W , we have

$$M = k W (\mu - \mu_s) \quad (1)$$

where k is a constant (different for different metals) and μ_s is also a constant which we find is virtually identical with the coefficient of friction of two surfaces of the given metal sliding against each other at similar loading. (Experiments in this laboratory by P V K Porgess, J N King and P S Dobson have shown however, that for the non metals graphite, molybdenum disulphide and sodium chloride, the M vs μ locus is curved.)

In considering the abrasive process theoretically, we conclude that if the abrasive particles were

Fig 2 Wear of 2 cm copper and tungsten specimens on various grades of emery paper (—●— copper 1 kgm load —x— tungsten 1 kgm load)

Fig. 3. The linear variation of M with μ for the copper and tungsten specimens: \times — \times , tungsten, 2 kgm. load, \bullet — \bullet , copper, 1 kgm. load.

spherical, and all those contacting the metal shared the load equally, then μ would indeed be very small, the ploughing component μ_p being correspondingly small and of the order suggested by Spurr and Newcomb's results (~ 0.1), but that it would be practically constant, independent of D . We find, in agreement with these views, that μ is, in fact, very small, ~ 0.15 (and thus μ_p still smaller), for metals such as copper and silver sliding under 1–2 kgm. load on a two-dimensional array of glass spheres of about 125 microns diameter ($\sim D$ for grade 2 emery) bonded on to a backing sheet (namely, "Scotchlite" reflective sheeting). Correspondingly, a negligible wear is observed in this case, although shallow, smoothly rounded grooves are formed, and little wear would be expected in view of the small inclination of the sphere surface to that of the metal near the contact, due to the low degree of indentation into the metal in the present conditions.

On the other hand, for metals such as copper and silver sliding on a glass-paper or emery-paper sheet having this order of particle diameter (~ 125 microns), μ was high, ~ 0.8 , and practically independent of D for values of D between 50 and 150 microns. We conclude (see below) that of this μ , μ_p is about 0.5, much higher than Spurr and Newcomb's suggested. The wear rate was also high and approximately constant for D within this range. The individual angular abrasive particles caused grooves in a smooth silver surface (sliding under 1 kgm. load) largely by removal of more or less curved, waved or coiled strips of metal of length up to about ten times the groove width (which was $\sim 1/3$ – $1/7$ of D). These metal strips were often observed still integral with the metal at the front ends of the grooves. The high μ and M that we observe in this range of D is thus evidently due to the emery (or glass) particles being mostly angular (as can be seen in the microscope) and not spherical.

Theoretically, if n pyramidal or conical particles share the load W equally and are indented into the metal surface with their axes along the direction of the loading, then the sum of the areas of contact (between the particles and the metal) projected on to the plane normal to the loading direction must be constant and equal to W/p_m , where p_m is the maximum flow pressure of the metal. Thus, n is determined by W and p_m , together with θ , the angle

between the pyramid axis and one of the radial edges. For square pyramids, azimuthally randomly oriented, we find that

$$\mu = \mu_p + \mu_a = (2/\pi) [\sqrt{2}(p'_m/p_m) \cot \theta + (s/p_m) (2 \operatorname{cosec}^2 \theta - 1)^{1/2}] \quad (2)$$

and for equilateral triangular pyramids:

$$\mu = \mu_p + \mu_a = (2/\pi) [2.25(p'_m/p_m) \cot \theta + 1.473 (s/p_m) (1.333 \operatorname{cosec}^2 \theta - 1)^{1/2}] \quad (3)$$

while for conical particles

$$\mu = \mu_p + \mu_a = (2/\pi) [(p'_m/p_m) \cot \theta + (s/p_m) \operatorname{cosec} \theta] \quad (4)$$

where μ_a is the adhesion- or shear-component of μ , s is the tangential force required to shear unit area at the operative surface where shear occurs, and p'_m is the apparent p_m for forward ploughing against an increased pile-up of metal ahead of the moving particle. We conclude that s/p_m is about 0.3, that is, about equal to the coefficient of friction of the metal (oxide) on the metal (oxide), that is, μ_0 . Although $p'_m > p_m$, we can take these as approximately equal.

To account for the observed maximum $\mu \sim 0.55$ for tungsten (see Fig. 1), the mean θ would thus have to be about 70° for square pyramidal particles ($2\theta = 140^\circ$, minimum profile angle 125°) giving $\mu_p = 0.33$, 75° for triangular pyramidal particles (min. profile angle 137°) giving $\mu_p = 0.37$, and 62° for cones (profile angle 124°) giving $\mu_p = 0.33$. This corresponds well to the sort of obtuse angularity of the particles mostly seen in the microscope. This theory thus accounts well for the observed μ , which is much larger than for the case of the more shallowly indenting spheres, which approximate to cones of nearly 180° angle, that is, $\theta \sim 90^\circ$.

The constant value of μ observed at $D > 70$ microns appears, in general, to be smaller the harder the metal, for example, ~ 0.78 for copper, nickel, silver and gold, 0.65 for platinum, ~ 0.6 for molybdenum, chromium, iron, beryllium, and ~ 0.55 for tungsten. This variation is partly associated with the differing values of s/p_m (this variation is apparently small), but it appears to be mainly due to the ratio p'_m/p_m varying from 1 for the hard metals such as tungsten to ~ 1.5 for the softer metals such as copper, silver and tin.

The above model could be made more general by including the case of pyramids or cones having their axes inclined away from the direction of loading, but this would still be only an idealized approximation to the extremely complex actual case of irregularly shaped abrasive particles. Our model shows, however, that in the absence of clogging, μ is independent of the particle size of the abrasive, and that μ_p forms the major part of the observed total μ .

Now considering the wear rate, M , suppose a part, fW (where $0 < f < 1$), of the load W is supported on n identical emery particles, and the remaining load $(1-f)W$ is supported on metal-to-metal contacts. Let A_1 be the groove cross-sectional area (normal to the direction of sliding), A_0 being the equivalent part of this area corresponding to metal removed from the groove space but finally remaining on the specimen (for example, as the pair of piled-up ridges at the sides of the groove, and also as re-adhering wear particles). Then we conclude that

$$M = (fW\rho/p'_m) \propto \{1 - (A_0/A_1)\} \mu_p \quad (5)$$

$$= (W\rho/p'_m) \propto \{1 - (A_0/A_1)\}$$

$$[1 + (\mu - \mu_0)/\mu_p]^{-1} (\mu - \mu_0) \quad (6)$$

where ρ is the density of the metal p_m is the maximum flow pressure across A_1 to cause ploughing, and α is the fraction of the emery particles shaped and oriented favourably for producing wear particles. Comparing the observed linear form, Fig 3 and equation (1), with this theoretical relation (6) shows that A_0/A_1 is independent of the emery particle diameter. Using an equation such as (2), (3) or (4) to express μ_p in terms of θ , equation (5) gives M directly in terms of θ and the properties of the metal, that is, ρ , p_m , p_m , etc.

Since $M = \alpha n p (A_1 - A_0)$, and $n A_1 = f W / p_m$ we may write as an alternative to equation (5) a more direct expression of M in terms of the properties of the metal

$$M/p = \alpha K (f W / p_m) \{1 - (A_0/A_1)\} \quad (7)$$

$$= C (f W / H_D) \{1 - (A_0/A_1)\} \quad (8)$$

where K is a constant defined as A_1 , divided by the horizontal component A_h (that is, normal to the direction of loading) of the mean contact area per particle supporting the load during sliding—thus K depends on the shape of the particles, H_D is the diamond pyramid indentation hardness number of the immediate surface region (which is very heavily work hardened by the ploughing action of the abrasive particles), and C is a constant. Equation (8) shows that if A_0/A_1 is the same for all metals, at constant W , then

$$(M/p) H_D = \text{constant} \quad (9)$$

Our results in Table 1 give an approximate check on the constancy of A_0/A_1 for various metals using equation (7) to calculate $M p_m / W = \alpha K \{1 - (A_0/A_1)\}$, taking $f = 1$ and $p_m =$ three times the ultimate tensile strength for the metal in a heavily work hardened state (cf. $p_m \sim 90$ kgm/mm² for copper)*. It is seen that $\alpha K \{1 - (A_0/A_1)\}$ is of the same order for copper silver platinum and iron. The small differences are probably due to the uncertainty of the value of p_m applicable to the work hardened surface layer and the more widely differing results for aluminium, molybdenum and tungsten seem likely to be mainly due to this uncertainty in p_m .

Further circumstantial evidence of the constancy of A_0/A_1 for all pure metals is given by our interpretation of the results of Kruschov† (see below). The constant K depends on the shape of the abrasive particles and is ~ 0.5 in our case where $0 \sim 60 \sim 70^\circ$, and $0.5 < \alpha < 1$ from direct observation, and by consideration of the experimental $M/(\mu - \mu_0)$ values

Table 1

| Metal | W | Mo | Fe | Cu | Ag | Pt | Al |

in the light of equation (6). The values of $M p_m / W$ in Table 1 thus indicate that $A_0/A_1 > 85$ per cent

Khruschov† showed experimentally that for all metals in the annealed state (of hardness H_D), sliding on the same grade of abrasive cloth (corundum particles $\sim 80 \mu$ diameter) under the same load the volume of wear per unit length, M/p in our notation, is proportional to $1/H_D$. He further observed however, for various metals that M is actually practically independent of the degree of work hardening of the initial metal, and as he concluded this shows that the process of abrasion work hardens the surface region of the metal (which undergoes further abrasive wear) to about the maximum possible extent, though this maximum hardness (H_D)_{max} was not defined. Our theoretical result (8), that (for not too small distances of abrasion) M/p should be proportional to the reciprocal of this hardness of the abraded surface, can be considered as showing in conjunction with Khruschov's observation of $M/p \propto 1/(H_D)$ that this (H_D) _{max} is practically proportional to (H_D) for all pure metals the factor A_0/A_1 being also the same for all pure metals.

The work described has been carried out under the terms of the extra departmental contract between the Mechanical Engineering Research Laboratory of the Department of Scientific and Industrial Research and the Imperial College of Science and Technology, University of London.

A CAPACITANCE METHOD FOR FOLLOWING VINYL POLYMERIZATIONS INITIATED BY γ -RAYS

By G. J. K. ACRES and F. L. DALTON

Isotope Research Division, Warrington Radiation Laboratories, U.K. Atomic Energy Authority

DILATOMETRY has long been accepted as the most satisfactory method of following the course of vinyl polymerization. The change in volume as the monomer polymerizes is measured by following the fall in the level of the monomer in a capillary tube using a cathetometer. Direct optical measurement is

impossible when radiation is used for initiation, and although the use of a mirror system is sometimes feasible, parallax errors tend to reduce the accuracy of the method. Also, since polymerization reactions often require several hours for their continuous recording method is

A dilatometer in which the capillary is filled with mercury was developed by Schultz and Harborth¹ to obviate difficulties in following the movement of the surface of highly viscous fluids, and later modified by Burnett for use under high vacuum², we have adapted this dilatometer by using the falling-mercury column as one plate of a condenser, the other plate being a sheathed metal rod parallel to the capillary. Polymerization is followed by measuring the change in the capacity of this condenser using a commercially available capacitance bridge and feeding the output signal to a recorder. The equipment has been designed for use with the radiation sources at Wantage Radiation Laboratory these have been described in detail by Dove, Murray and Roberts³.

The sample is prepared in a breaker-seal tube under high-vacuum conditions and sealed off. Above the breaker seal a B 7 socket is attached and the sample may be connected to the body of the dilatometer by means of this joint as shown in Fig 1. The bore of tap T_1 is filled with mercury, and with T_2 open and T_1 closed the apparatus is connected to the high-vacuum line and evacuated via the B 7 cone A. Reservoir R_1 is filled with mercury and tap T_2 closed. T_1 is then partly opened and the mercury in R_1 allowed to spray slowly into reservoir R_2 . This procedure was found to 'flash off' any small quantities of air trapped in the mercury. After the mercury has run into R_2 , T_2 is opened cautiously and the mercury allowed to flow into the dilatometer until it reaches the level B. The seal is broken by an upward movement of the breaker C, T_2 re-opened and mercury allowed to fill the entire vessel. Air is allowed into the system above A, the reaction vessel removed from the high-vacuum line and reservoir R_1 detached. A capillary tube of appropriate diameter fitted with a B.7 socket and with an earthing connexion sealed through it is held by two short lengths of rubber tubing against a $\frac{1}{8}$ -in. steel rod covered in polythene. The polythene shield prevents fluctuations due to surface adsorption of water vapour by the capillary tube. The steel rod has a small metal plate attached to one end for connexion to the capacitance bridge.

Fig 1. Diagram of dilatometer

The capillary and fittings are shown in Fig 2. This capillary is connected by means of its B 7 socket to A. picein wax is used to seal the joint. By applying compressed air pressure above R_2 and opening T_2 , mercury is forced through A into the capillary tube. T_2 is then closed and the whole apparatus immersed in a water thermostat in the radiation source.

It was found essential that the measuring capillary should be above the surface of the thermostat water, since otherwise a balance of the proximity meter could not be obtained, also, since stabilized glass tanks were not available, it was an advantage to have the capillary above the level of the thermostat tank so that the initial and final mercury-level could be accurately measured with a cathetometer.

Fig 2. Capillary and electrode

Fig 3 shows the dilatometer in position. The capacitance bridge used was a Fielden PM2 proximity meter (Fielden Electronics, Ltd, Wythenshawe, Manchester). This instrument offsets the large constant capacity of the system and measures only changes in capacity. Since the length of the probe is only 6 ft the meter remains inside the radiation cell and is shielded by conventional interlocking 4-in. lead bricks. The sensitivity may be changed during the run if the fine sensitivity control is removed from the instrument case and mounted outside the cell. This enables the first few per cent of reaction to be followed in detail at high sensitivity, if the sensitivity is then lowered an overall conversion curve may be obtained from the same sample. To enable the proximity meter to be attached to a recorder, a 10-ohm resistance was put in series with the 1-m amp meter of the instrument and the voltage drop across this resistor fed to a Sunvic single-pen 10-millivolt recorder, clearly other values of this resistance may be chosen to suit any available millivolt recorder. To obtain stable readings of the recorder it was found essential to earth the mercury and this was done by connecting E (Fig 2) to the earth of the mains. Earthing of the thermostat tank, clamps and any other metal near the apparatus was found to be necessary. A series of calibration graphs

were made for various settings of the sensitivity control and various capillary diameters. The dependence on sensitivity setting for a 1 mm capillary is shown in Fig 4. The use of narrower capillaries tends to lower the sensitivity of the equipment slightly. In practice, initial and final mercury levels were measured with a cathetometer in order to avoid any slight errors in the sensitivity setting.

At Wantage the apparatus has been used to follow the emulsion polymerization of styrene and methyl methacrylate, and the preparation in emulsion of graft co polymers of polystyrene and methylmethacrylate and poly methylmethacrylate and styrene. It has also been used to follow the bulk polymerization of acrylonitrile and the graft polymerization initiated by gamma rays of acrylonitrile on to poly-dimethyl siloxanes. In use, the following precautions have been found necessary:

(1) A stable power supply is required, and it is therefore advisable to supply the proximity meter from a voltage stabilizer. Mains fluctuations at

Fig 4 Calibration plot for 1 mm capillary

Wantage are exceptional, however, and this precaution may not be generally necessary. (3) The proximity meter should be allowed at least 30 min. to warm up before each polymerization run. (3) It is essential to earth the mercury, the thermostat tank, source tube and other metal equipment near the capillary to the instrument earth.

The equipment has been used to measure contractions 0.6–30 cm. in capillaries the diameters of which range from 2 mm. to 0.5 mm. The limit of 0.6 cm. is imposed by the maximum sensitivity of the proximity meter. Contractions greater than 30 cm. have not been used in order to keep the size of the capillary small and for contractions greater or less than these values for any given capillary, change in capillary diameter was used. The limit of this process, so far as small contractions are concerned, appears to be the stability of the thermostat tank, since if the capillary is made too narrow, fluctuations due to the slight rise and fall in temperature of the tank amounting to perhaps 0.01 or 0.02 deg. C, are observed. Greater sensitivity may also be obtained by increasing the diameter of the steel rod (Fig 3).

PRODUCTION OF COLICINE BY SINGLE BACTERIA

By H. OZEKI, DR. B. A. D. STOCKER and HELENE DE MARGERIE

Guinness-Lister Research Unit, Lister Institute of Preventive Medicine,
London S.W.1

COLICINES are bactericidal substances produced by certain strains of Enterobacteriaceae and active on others¹. Colicins in many respects resemble bacteriophages; but, unlike them, do not multiply in the cells they kill. A single particle or molecule of colicin therefore does not produce a 'colony' (plaque) in the confluent growth of a sensitive strain, as does a single phage particle. From the analogy with the production of phage by lysogenic strains it has been surmised that all the colicin produced by a colicinogenic culture, either spontane-

ously or after induction² by ultra violet irradiation is synthesized and released by a fraction of the bacterial population, and that these cells are in consequence non-viable. No direct test of this hypothesis has been possible because colicin production has hitherto been tested only by observation on the antibiotic activity of mass cultures. We have now demonstrated the release of colicin by individual bacteria: (1) through the production by single bacteria of small clear spots in the confluent growth of a colicin-sensitive strain. (2) by the bactericidal

action of products released into micro-drops of broth by single colicinogenic bacteria isolated by micro-manipulator. The results obtained by these techniques support the above hypothesis.

The colicinogenic strains used were derivatives of *Salmonella typhimurium* strain LT2 made colicinogenic by growth in mixed culture with colicinogenic *Escherichia coli* or *Shigella* strains¹, or by phage-mediated transduction². The colicine-sensitive indicator strains were *E. coli* strain ϕ^3 and antibiotic-resistant mutants derived from it.

To demonstrate the clear spots caused by the colicine released by single bacteria we used a modification of the soft agar layer method used in phage work. 3 ml of soft agar (0.35 per cent) seeded with about 10^8 cells of the indicator strain and about 10^4 cells of a young broth culture of *S. typhimurium* producing colicine E2⁴ were poured on to a nutrient agar plate, after 5 hr incubation at 37° about 100 small clear spots, 0.2–0.8 mm in diameter, were visible in the confluent growth of the indicator strain. No such spots were produced by cells of a non-colicinogenic *Salmonella* strain, nor with an indicator strain resistant to colicines of the E group. Colicine E2 is destroyed by trypsin, crystalline trypsin (200 $\mu\text{g}/\text{ml}$) in the soft agar prevented the appearance of clearings. Although the spots looked like phage plaques, no lysis was observed when they were cut out and tested on a fresh plate of indicator bacteria.

It thus appeared that the clear spots resulted from the production of colicine E2, either by the colicinogenic bacteria inoculated, or, perhaps, by their descendants. The following results show that a clear spot can be produced by the colicine synthesized and liberated by a single bacterium.

Colicinogenic bacteria when plated with a streptomycin-resistant indicator in soft agar containing sufficient streptomycin to prevent their growth still produced some clear spots. Similar results were obtained with chloramphenicol. Furthermore, some clear spots were produced even when the colicinogenic cells had been killed by treatment with chloroform for 5 min at 37° before inoculation. The number of clear spots produced in the presence or absence of streptomycin was directly proportional (about 1 per cent) to the number of cells of the colicinogenic strain incorporated into the soft agar layer. Blender treatment, sufficient to break up any cell clumps, applied to the colicinogenic culture just before its inoculation into the soft agar, did not affect the number of clear spots produced. The number of clear spots appearing in the presence of streptomycin was 10- to 100-fold less than without it, this suggests that most of the clear spots formed in the absence of streptomycin are produced by bacteria which synthesize colicine on the plate, but that there are a few cells in the culture each of which at the time of plating already contains enough colicine to produce a clearing.

Clear spots were produced, either in the presence or absence of streptomycin, even when the colicinogenic cells had been grown in broth containing trypsin, provided the trypsin was removed by washing, or neutralized by soy-bean trypsin inhibitor, at the time of plating. As all free colicine in the inoculum culture was destroyed by the trypsin, the colicine causing a clear spot cannot have been adsorbed from solution by a cell of the inoculum culture, and released later, a hypothesis proposed by Frédéricq⁵ to explain the small plaque-like clearings

he observed when dilutions of a colicinogenic culture killed with chloroform were plated with a colicine sensitive indicator strain, it now seems probable that these clearings, like those here reported, resulted from production of colicine by single bacteria.

In certain colicinogenic strains, colicine production is inducible by ultra-violet irradiation¹. The number of clear spots produced by a strain colicinogenic for E2 was much increased by irradiation before plating, if cells irradiated for a time which reduced the viable count by about 70 per cent were plated in a streptomycin soft-agar layer 90 min later, the number of clear spots which appeared was half or more of the total number of colicinogenic bacteria inoculated, determined in a counting chamber.

We propose the term 'lacuna' for the clear spots produced by the colicine released by a single bacterium, in distinction from a phage 'plaque'. The soft agar of an area 0.8 mm in diameter contains about 6,500 colicine-sensitive bacteria at the time of inoculation, the presence of lacunae of this size indicates that some colicinogenic bacteria liberate at least 6,500 bactericidal particles of colicine E2.

The production of colicine by individual bacteria has also been demonstrated by micromanipulative isolation. Cells of the colicine-sensitive indicator strain grew as non-motile filaments, easily distinguishable from the short motile cells of *Salmonella typhimurium*. Cells of the indicator strain inoculated into droplets of broth containing colicine E2 failed to multiply, and became abnormal in appearance, showing alternate bright and dim segments when examined by low-power dark-ground microscopy, cells of a colicine-E2-resistant mutant of the indicator strain multiplied normally in such droplets. To test the production of colicine by individual bacteria, a strain of *S. typhimurium* colicinogenic for colicine E2 was 'induced' by ultra-violet light and incubated for 30 min. at 37° in broth, containing trypsin (500 $\mu\text{g}/\text{ml}$) to inactivate extra-cellular colicine. The irradiated cell suspension was then introduced into a micromanipulation chamber, and each of a series of droplets of broth with trypsin inhibitor 2 mg/ml was inoculated with a single bacterium from the suspension, volumes of the suspension not containing any cells were added to control droplets. 2 hr later the colicinogenic bacterium had multiplied in about 20 per cent of the droplets, in the remainder it had not multiplied but was still visible. The proportion of single bacteria able to multiply in the micro-drops agreed well with the survival-rate of the irradiated suspension inferred from the ratio of viable and total counts. Three to twenty cells of the indicator strain were then added to each droplet. In about 60 per cent of the droplets in which the colicinogenic bacterium had failed to multiply the indicator bacteria added later did not multiply and instead developed the characteristic abnormal appearance. In the remaining 40 per cent the indicator bacteria multiplied normally, as they did also in the control droplets which had received medium, but no bacterium, from the suspension of irradiated colicinogenic bacteria. In droplets in which the colicinogenic bacterium had multiplied, the indicator bacteria at first multiplied, showing absence of colicine, but later ceased to grow, presumably as a result of colicine being released by one or more of the large population of colicinogenic bacteria then present. About 50 per cent of the individual bacteria tested were shown by this method to release colicine, in platings from the same irradiated suspension the

ratio of the number of clear spots to the total number of bacteria was about 6/10.

The micromanipulation experiments described above indicated that all or nearly all the cells of an irradiated culture which release colicine E2 are non-viable. To see whether this was also so for the spontaneous production of colicine E2, about 1,000 cells of a chloramphenicol sensitive colicinogenic strain were plated in a soft agar layer of a defined medium containing chloramphenicol, together with a chloramphenicol resistant indicator strain, the latter was nutritionally exacting, so that it could multiply to only a small extent in the defined medium provided. After 5 hr incubation, twelve lacunae were visible in the thin confluent growth of the indicator. After overnight incubation about 1,000 small colonies of the nutritionally less exacting colicinogenic strain appeared, the chloramphenicol concentration having fallen by diffusion into the base layer of agar, below the level required to inhibit its growth. No colonies developed at the centres of the twelve lacunae marked earlier. It is concluded that the bacteria which produced these clearings by releasing colicine were unable to multiply.

The production of lacunae has been used for a number of other investigations which will be reported in detail elsewhere. *Salmonella typhimurium* strains producing colicines I, B, K and E1 produce lacunae, of sizes about the same as with colicine E2. When overnight broth cultures were tested in soft agar containing streptomycin the numbers of lacunae produced per million bacteria plated were approximately: colicine E2, 1,000; I, 0.2; B, 200; K, 300; and E1, 1,000. The ratio varied in cultures of different ages, for example it increased 10 fold when an overnight culture of a strain producing colicine E2 was diluted in broth and incubated for 1 hr at 37°. After ultra-violet irradiation the fraction of bacteria producing lacunae increased to about 0.5 in strains producing colicines E1 and E2; no increase was detected in a strain producing colicine I.

We thank Prof P. Frédérlec for the provision of colicinogenic strains.

PERMANENT SET, SUPERCONTRACTION, AND UREA-BISULPHITE SOLUBILITY—THE PROTON-TRANSFER NATURE OF SOME CHANGES IN KERATIN AND THE ANALOGY WITH MUSCLE CONTRACTION

By DR. P. T. SPEAKMAN

Department of Textile Industries University of Leeds

DURING the reaction of cystine residues in keratin with OH⁻ ions sodium bisulphite, etc. the proportion of

contributing to the resonance hybrid of the peptide groups hydrogen bonded to each other in the protein network and eventually to a carbonyl oxygen atom of the cystine residue, can alter. An increase in the proportion of II (that is, an increase in the negative charge on the oxygen atom) will affect the strength of the hydrogen bonds between peptide groups electrostatically, also it can be shown that an increase in the strength of the individual hydrogen bonds will follow as more peptide groups are attracted into the co-operating, hydrogen bonded system. The stability of permanently set keratin, and of keratin treated with alkali with a decreased solubility in urea bisulphite solutions, seems likely to be caused by an increase in the strength of the hydrogen bonds between protein chains, caused in this way. The analogy between muscle contraction and supercontraction of keratin suggests a mechanism of contraction of muscles containing sulphur in which disorientation and contraction of the muscle follows a weakening of the hydrogen bonds between peptide groups by reagents which react with sulphhydryl groups. Re-orientation of the muscle would follow an increase in the charge on the oxygen atoms of the peptide groups during the reverse reaction.

In some early experiments on permanent set¹ a keratin fibre was extended in water and treated under tension with, for example steam boiling buffer solutions, or sodium sulphite solution. The treated fibre was immersed without tension for an arbitrary period (1 hr) in boiling water, and if the fibre was to some extent stabilized in its extended form and its length remained greater than the initial length then it was said to be permanently set. If it was less supercontraction had occurred. Cross linkages between the keratin chains are broken by the treatments, thus allowing the chains to rearrange in the stretched fibres. If no new cross linkages are formed then a change in the arrangement of the uncross-linked protein chains after immersion in boiling water causes supercontraction. If new cross linkages are formed in the treatments, then the chains are to some extent held in their positions in the extended fibre thus causing permanent set. A chemical treatment which decreases the solubility of keratin in urea bisulphite solutions² is similarly most plausibly explained by new resistant linkages between protein chains.

Breaking of cystine disulphide bonds is an essential preliminary to permanent set in wool but work in Australia on fibres containing reduced and alkylated cystine residues³, and on the hurefringence and contraction in lithium bromide solutions of set fibres⁴ shows that it is an over-simplification to suggest that permanent set is entirely due to new covalent cross linkages formed after reduction or hydrolysis of the cystine residues. Two cross linkages which have been

extended fibres are set, the X-ray diffraction photograph of set β -keratin, compared with unset β -keratin¹⁵, shows a sharpening of the backbone reflexion, confirming the orientation of more protein chains into the strict β configuration. Davies, Evans and Lumley Jones¹⁶, using methyl acetamide in carbon tetrachloride, have shown that the shift in the hydrogen-bonded NH vibration infra-red absorption frequency away from the non-hydrogen-bonded NH vibration frequency is increased from approximately 120 cm⁻¹ to 190 cm⁻¹ as the concentration of amide is increased. The shift can be attributed to an increase in the number of amide groups hydrogen-bonded together in each linear aggregate. The difference between the absorption frequencies of the NH vibration in non-bonded and hydrogen-bonded amide groups is proportional to the energy of the hydrogen bond, and therefore in the experiments of Davies, Evans and Lumley Jones the energy has been increased 60 per cent by increasing the number of co-operating hydrogen-bonded amide groups in each linear aggregate. Thus the stability of a hydrogen-bonded protein structure can be increased by bringing more peptide groups into the co-operating hydrogen-bonded system. If it becomes possible to examine the infra-red spectrum of unset β -keratin the NH vibration frequency should show a smaller shift from the non-hydrogen-bonded NH frequency than the NH vibration frequency in set β -keratin where, according to the present theory, the protein chains are oriented so that there are more co-operating peptide groups in each hydrogen-bonded series.

If the hydrolysis of cystine in steam, like the hydrolysis by OH⁻ ions, involves ionization of a proton at the α -carbon atom, then the observed facts of steam setting are readily explained. At first, in the extended fibre, the hydrogen bonds are weakened by the increased polarization of the peptide groups. Immersion of the fibre without tension in boiling water after up to 15 minutes in steam causes supercontraction. Longer treatment in steam allows further orientation of the protein chains, and more co-operating peptide groups increase the strength of the individual hydrogen bonds, thus causing permanent set¹⁵. Treatment of extended keratin fibres in boiling borate buffer solutions¹ (pH 9.2) for 30 min causes permanent set, orientation strengthening the individual hydrogen bonds. Less drastic treatment with phosphate buffers from pH 8 to 10 for 1 hr at 50° C¹⁷ or 20 per cent potassium hydroxide solution at 28.5° C for 3 min¹⁸ causes weakening of the hydrogen bonds by increased polarization of the peptide groups, without sufficient subsequent orientation to strengthen the hydrogen bonds, and thus supercontraction occurs under these conditions.

Swan⁶ has shown that the hydrogen atom attached to the α -carbon of cystine is not involved in the reduction of cystine by sodium sulphite. However, sulphur can take part in hydrogen bonding¹⁹, and the most plausible hydrogen bond in cystine residues would seem to be

The approach of a negative ion, SO₃²⁻ or HSO₃⁻, to sulphur atom *b* would induce a positive charge on *b* and a negative charge on *a*. In turn, the polarity

of the peptide group would be increased. The negative charge on *a* will be further increased if the cysteine residue formed in the reduction is ionized, and in fact the setting reaction does appear to be catalysed by alkali¹⁷.

The changes in the polarization of the peptide group and other peptide groups hydrogen-bonded to it will cause immediate weakening and eventual strengthening of the hydrogen bonds as in steam setting and setting in alkaline solutions.

During the synaeresis of actomyosin after adding adenosine triphosphate, the X-ray diffraction pattern shows in certain conditions the appearance of a faint 'cross- β ' reflexion which is typical of supercontracted keratin²⁰. This suggests that there may be some similarity between the contraction of components of muscle containing sulphur and keratin supercontraction. Reaction with sulphhydryl groups of muscle protein could alter the stability of the hydrogen-bonded network so that the chemical energy from a reversible, high standard free energy transphosphorylation, for example, liberated as kinetic energy, would cause disorientation of the protein structure and contraction. Then the reverse phosphorylation might induce negative charges on the peptide carbonyl oxygen atom and thus re-orient the muscle component into its original α -helical form.

This theory of permanent set, supercontraction, and urea-bisulphite solubility of keratin is put forward to explain those experimental facts²⁻⁵ not fully explained by the early theories of permanent set^{1,15}. There is no doubt, however, that all the chemical forces—covalent, electrovalent, van der Waals, and not merely hydrogen bonding—are involved in the three experimental phenomena considered.

I am grateful to Prof W. T. Astbury for many suggestions during helpful discussions of this work.

INACTIVATION OF SOME ANIMAL VIRUSES BY HYDROXYLAMINE AND THE STRUCTURE OF RIBONUCLEIC ACID

By DR. RICHARD M. FRANKLIN and DR. EBERHARD WECKER

Max Planck Institut für Virusforschung Tübingen Germany

IN the course of some studies on factors which might stabilize infectious ribonucleic acid isolated with phenol from animal viruses, it was found that hydroxylamine inactivates the infectious ribonucleic acid extracted from mouse encephalomyelitis virus (Table 1). In addition, several animal viruses, all of which contain ribonucleic acid, proved to be sensitive to hydroxylamine (Table 1).

Hydroxylamine may act on animal viruses by affecting (1) viral protein, (2) viral ribonucleic acid, or (3) both viral components. Several types of experiment were performed in order to locate the site of action of hydroxylamine. In the first type of experiment, mouse encephalomyelitis virus was treated with hydroxylamine and then ribonucleic acid was extracted. If hydroxylamine had reacted with the ribonucleic acid of the virus, then the extracted ribonucleic acid should be non-infectious. This type of experiment must be distinguished from that described in Table 1 where infectious nucleic acid is first extracted from virus particles and then treated with hydroxylamine. The experiments were carried out as follows. Mouse encephalomyelitis virus was incubated in 1 M hydroxylamine at 22° C and pH 7. A control preparation containing no hydroxylamine, was incubated under the same conditions. The virus preparations were treated for various periods of time in the individual experiments. After dialysis of both samples, aliquots were assayed for virus infectivity to determine the virus survival ratio. The same samples were treated with phenol at 42° C to extract ribonucleic acid.¹ Infectivity of ribonucleic acid was titrated by intracerebral inoculation in mice. The ratio of the infectivities of ribonucleic acid extracted from treated virus to that extracted from control virus should be the same as the virus survival ratio if hydroxylamine inactivates the virus only by alteration of viral ribonucleic acid. Highly variable results were obtained, but the average virus survival ratio was only four times higher than the average survival ratio of the extracted ribonucleic acid. Considering the many manipulations involved in these experiments, the results indicate that hydroxylamine acts on mouse encephalomyelitis virus by altering the viral ribonucleic acid. This conclusion is also supported by the fact that mouse encephalomyelitis virus is inactivated at a rate comparable to that of infectious ribonucleic acid isolated from the virus (Table 1).

The second type of experiment to locate the site of action of hydroxylamine tested the effect of this compound on several activities of viral protein. A mouse encephalomyelitis virus preparation inactivated by treatment with 1 M hydroxylamine at 22° C for 24 hr and then dialysed for 24 hr had the same complement fixing activity against a rabbit antiserum to mouse encephalomyelitis virus

Table 1 THE INACTIVATION OF SOME ANIMAL VIRUSES AND ANIMAL VIRUS RIBONUCLEIC ACID BY HYDROXYLAMINE

1.4 M solution of hydroxylamine hydrochloride is adjusted to neutral pH by mixing with an equal part of 24 per cent sodium hydroxide. This solution is mixed with an equal part of infectious material and incubated for 15 min at 22° C. For the inactivation of viruses the reaction is stopped by 1:5 dilution in phosphate buffered saline (ref. 16) at 4° C and excess hydroxylamine is removed by dialysis against phosphate buffered saline for 24 hr. For inactivation of infectious ribonucleic acid the reaction is stopped and hydroxylamine removed by precipitation of the ribonucleic acid with alcohol. The virus infectivity was measured by plaque test (ref. 17) and the infectivity of ribonucleic acid from mouse encephalomyelitis virus was titrated by intracerebral inoculation in mice (ref. 1).

| Infectious material | Survival ratio* |
|--|--|
| Infectious ribonucleic acid from mouse encephalomyelitis virus | 2.6×10^{-1} 1.8×10^{-2} |
| Mouse encephalomyelitis virus | 2×10^{-1} |
| Fowl plague virus | 2×10^{-1} |
| Swine influenza | 2×10^{-4} |
| Western equine encephalomyelitis virus | 3×10^{-1} |

* Title of treated/litre of control

as a control preparation. Thus treatment of mouse encephalomyelitis virus with hydroxylamine results in an alteration of the infectivity of the ribonucleic acid without major alterations in the serological properties of the protein. In order to study the effect of hydroxylamine on other proteins of animal viruses, a fowl plague virus concentrate was treated with 1 M hydroxylamine for 24 hr resulting in complete inactivation. After 24 hr dialysis, the haemagglutinating activity was the same as that of a control. Further, the enzymatic activity of the virus, measured by elution from red blood cells at 37° C, was identical in treated and control preparations. The complement fixing ability of the treated preparations was the same as that of the control when measured with anti fowl plague serum. Hence, as in the case of mouse encephalomyelitis virus, hydroxylamine had not caused any detectable changes in the viral protein, at least in the peripheral protein.

Hydroxylamine also inactivates certain bacterial viruses, but the action in this case is on a protein component, probably resulting in the rupture of thiol ester bonds in the protein of the tail fibres.² The activation energy of this process³ is approximately 10 kcal/mole. To contrast this with the inactivation by hydroxylamine of animal viruses the activation energy for the inactivation of western equine encephalomyelitis virus was determined over the temperature range 20–44° C. A value of approximately 4 kcal/mole was found. The difference observed in the activation energies for the inactivation of bacterial viruses and western equine encephalomyelitis virus indicates that different chemical processes may be involved in the two cases.

(Note added in proof The activation energy for inactivation of mouse encephalomyelitis virus is 15.6 kcal/mole. Since mouse encephalomyelitis virus and mouse encephalomyelitis ribonucleic acid are inactivated at the same rate, this must be the energy associated with the reaction of ribonucleic acid with hydroxylamine. This is similar to the energy for splitting thiol-ester bonds and may further suggest that an ester bond is split from ribonucleic acid by hydroxylamine. The previously determined activation energy for inactivation of western equine encephalomyelitis virus may then represent a secondary reaction, perhaps an alteration of viral lipid.)

A direct attack on the nature of the reaction of hydroxylamine with ribonucleic acid gave little positive information. 'Model' ribonucleic acid was prepared from rat liver and calf liver by extraction with phenol at 4° C, using phosphate-citrate buffer at pH 5 in order to prevent the simultaneous extraction of deoxyribonucleic acid. After alcohol precipitation, followed by precipitation with 1 M sodium chloride, the nucleic acid obtained consists of a two-component system with molecular weights $\sim 2 \times 10^6$ and $\sim 6 \times 10^5$, respectively (cf ref 4). This ribonucleic acid was treated with hydroxylamine for 24 hr or 48 hr and excess hydroxylamine was removed by repeated alcohol precipitation of the ribonucleic acid. There was no degradation of ribonucleic acid, as revealed by analytical ultracentrifugation. Further, paper chromatographic and paper electrophoretic studies of the products of alkaline and acid hydrolysis showed no differences from those of untreated ribonucleic acid. Thus hydroxylamine does not seem to split the phosphate-sugar backbone of ribonucleic acid or alter any of the bases. If one of these processes was responsible for the inactivation of infectious ribonucleic acid, which has a $1/e$ value of 3.7 min, meaning that an average of one such inactivating event has occurred in each molecule in 3.7 min, then approximately 400 such inactivating events would occur per molecule in 24 hr. The failure to detect any changes after 24-48 hr with the methods used is strong evidence that inactivation did not occur by either of the above-mentioned processes. As a comparative example, the oxidative deamination of adenine, guanine and cytosine in ribonucleic acid by nitrous acid can be demonstrated chromatographically after a reaction time of about 20 hr.⁵

Recent studies on the chemistry of protein synthesis have shown that amino acids are bound to a ribonucleic acid of low molecular weight (soluble-ribonucleic acid) before being coupled together in a polypeptide chain.^{6,7} The amino-acid is bonded to soluble ribonucleic acid at a 2' or 3' hydroxy-position of the terminal ribose and this amino acyl ester bond can be split by hydroxylamine.⁸ It could be that a similar structure exists in some forms of high molecular weight ribonucleic acid and that such a structure is essential for the biological activity of ribonucleic acid in those cases. It would be difficult, however, to demonstrate the existence of an amino acyl ester in nucleic acid of molecular weight $\sim 2 \times 10^6$ since, by weight, the amino-acid represents ~ 1 part in 10^4 of nucleic acid. Therefore, this hypothesis must be investigated by some indirect approach.

One such approach is a comparison of the stability of the amino acyl-soluble-ribonucleic acid bond with that of the infectivity of ribonucleic acid from mouse encephalomyelitis virus (Table 2). The stability of infectious ribonucleic acid in the pH range 5-7 and the

instability at pH 8.6 correspond to the pH stability of an amino acyl ester bond. Control experiments on the degradation at pH 8.6 of 'model' ribonucleic acid from calf liver, measured by alteration of viscosity during a 48-hr period, showed that inactivation of infectious ribonucleic acid at pH 8.6 could not be due to alkaline hydrolysis of the phosphate-sugar backbone. Hydroxylamine inactivation of ribonucleic acid from mouse encephalomyelitis virus proceeds more rapidly at pH 7 than at pH 5.5 and this is also true for hydroxylamine splitting of the amino acyl ester bond to soluble-ribonucleic acid.⁸ In contrast, the reaction of hydroxylamine with activated amino-acids (mixed anhydrides in which the carboxyl group of the amino-acid is phosphorylated)⁹ occurs equally well⁸ at pH 5.5 and pH 7.0. Therefore, if an amino-acid or related compound is linked to the ribonucleic acid of certain viruses, as suggested by these experiments, then the bond should be similar to that between amino-acids and soluble ribonucleic acid (ester) rather than to that in activated amino-acids (mixed anhydride).

Table 2. A COMPARISON OF THE STABILITY OF AN INFECTIOUS RIBONUCLEIC ACID FROM MOUSE ENCEPHALOMYELITIS VIRUS AND THE AMINO ACYL ESTER BOND TO SOLUBLE RIBONUCLEIC ACID

| Infectious ribonucleic acid | Amino acyl ester soluble ribonucleic acid bond |
|---|---|
| Stable at pH 5 60° for at least 10 min 22° for at least 15 min | Reported to be stable in 0.15 HCl, as well as in the pH range 3-6 (ref 18) |
| Stable at pH 7 60° for at least 10 min 22° and 37° for at least 30 min | Unstable at pH 8.6, 37° Extrapolation of the data to 30 min $n/n_0 = 0.025$ (ref 18) |
| Unstable at pH 8.6 37° for 30 min $n/n_0 = 0.03$ | Reacts with 1 M NH_4OH at pH 7 to a greater degree than at pH 5.5 (ref 8) |
| 1 M NH_4OH , 22° $1^{\circ} = 0.25 \text{ min}^{-1}$ at pH 6.8 and 0.10 min^{-1} at pH 5.5 | |

* Assuming a first-order reaction, $dn/dt = -kn$, where n is the remaining activity at time t .

Not all animal viruses can be inactivated with hydroxylamine under the conditions described here. For example, Newcastle disease and mumps viruses, which are in one distinct sub-group of the myxoviruses¹⁰, are resistant to 1 M hydroxylamine at 22° C. Fowl plague virus and swine influenza virus, which belong to another sub-group¹⁰, proved to be highly sensitive (Table 1). These results suggest that there are differences in the nucleic acids of these two groups of myxoviruses, although all myxoviruses which have been chemically analysed, including Newcastle disease¹¹, fowl plague¹², and influenza¹³ viruses, contain ribonucleic acid. Herpes simplex, which may contain deoxyribonucleic acid¹⁴, also proved resistant to hydroxylamine. The resistance of some viruses to hydroxylamine inactivation may be further evidence that hydroxylamine attacks a special configuration in the nucleic acid component of certain viruses, since it appears that all nucleic acids have certain chemical properties, such as a phosphate-sugar backbone, in common. Thus it must be concluded that hydroxylamine does not alter any of the chemical bonds common to all nucleic acids.

The biological significance of this hypothetical ester bonded to infectious ribonucleic acid is not clear. One suggestion is that an amino acyl ester or some other acyl group in an ester linkage located at a terminal position on a ribonucleic acid chain would serve to limit the chain-length by providing the

information that the end of the chain had been reached. In any event, such a structure could serve to give the chain a direction in a more striking manner than that provided by the presence or absence of a terminal phosphate¹⁵. Moreover such a terminal ester group may serve as a pruning agent for certain biosynthetic reactions.

The theoretical and practical aspects of the phenomena described here are being investigated further and will be published in full detail elsewhere.

We gratefully acknowledge the many stimulating discussions with Profs G C Mueller, W Schäfer, G Schramm and R Dulbecco. This work was supported by the Deutsche Forschungsgemeinschaft.

AUXIN AND THE BULBING OF ONIONS

By DR. J. E. CLARK and PROF. O. V. S. HEATH

University of Reading Horticultural Research Laboratories, Shinfield Grange, Shinfield, Berkshire

DETAILED studies of those changes in the internal morphology and histology of onion plants which are characteristic of the process of bulb development in response to the combined stimuli of long days and high temperature led to the formulation of a speculative hypothesis in terms of a supposed 'bulbing substance' or hormone¹. We are now engaged in a study of the changes in growth-substance content of onion plants during bulbing, using modifications of the methods of paper partition chromatography combined with bioassay of growth substances first developed by Bonnet Clark *et al.*^{2,3} we are also studying the effects of externally applied auxin on bulb development.

When testing for an unknown chemical growth factor supposed to produce a specific effect on a certain organ of an intact plant it is desirable if possible to develop an assay method depending on the production under standard conditions of such an effect in the same or similar tissue. Thus one should, ideally, test a fractionated tissue extract for the presence of a 'flowering hormone' by its capacity to cause flower initiation in growing points, preferably kept under otherwise non-inductive conditions; the appropriate test for growth promoting hormones is one in which increase of growth is measured, rather than inhibition of growth or abscission of organs, for a bulbing substance the assay method should involve bulb development again preferably under non-inductive conditions. If this principle is ignored as is frequently the case irrelevant or misleading information may be obtained. For the comparison of amounts of known compounds in tissue extracts from plants in different treatments, the use of assay methods depending on irrelevant plant responses would however, seem to be justifiable if suitable precautions are taken to confirm that the compound concerned is in fact the one supposed.

For bioassay we have therefore used a modification of the wheat coleoptile cylinder test⁴ in an attempt to compare changes in the 3 indolylacetic acid content of onion plants during bulbing in long days with that of plants remaining in short days, but we have also

developed a method in which onion seedlings constitute the test material and show an increase in bulbing ratio (the ratio of the greatest diameter to the least) when supplied with a suitable growth substance in darkness. The onion seedlings as used for this bioassay have been found not only to give a marked bulbing response to long days but also to externally applied 3 indolylacetic acid in darkness. Seedlings at the 2 leaf stage of development, with roots and leaf blades removed ('seedling sections') rotated horizontally in darkness in a 1 per cent sucrose solution, show from 1 to 8 days an increasing bulbing ratio in the presence of added 3 indolylacetic acid (sodium salt, pH 7.0, at 1×10^{-4} M concentration or approximately 20 p.p.m.), whereas in sucrose alone there are no marked or consistent changes. Such a response is rapid at 25° C, much slower at 20° C and almost non-existent at 15° C, this resembles the effect of temperature on rate of bulbing in response to the stimulus of long days⁵. We have also found with intact seedlings growing in water culture in short days, a small but statistically significant ($P < 0.02$) increase in bulbing ratio due to the addition of 1×10^{-4} M 3 indolylacetic acid to the solution, as compared with seedlings not given 3 indolylacetic acid.

We have made a preliminary survey of the changes, caused by various periods in long days at different stages of development, in the growth substance content of onion plants. For this purpose plants of variety Ebenezer were grown from sets in sand culture in short days (less than 12 hr.) and transferred to long days (17 hr.) at the time of expansion of the tenth, fourteenth, eighteenth and twenty-fourth leaf. Samples were taken from long-day and short-day plants of the same age according to the plan shown in Table 1. Roots and leaf blades were removed and an ethanol extract made of the remaining tissue. The method of fractionation was that of Bonnet Clark *et al.*² and Larsen⁶ except that the pH was brought to 2.5 with 20 per cent orthophosphoric acid. Only the ether soluble, acidic fraction has so far been investigated in detail. Extracts were chromat-

Table 2 DISTRIBUTION OF INHIBITORY ACTIVITY IN ROOT HOMOGENATES

| Addition (0.5 ml) to reaction mixture | Glutamylhydroxamate (μ moles) | |
|--|------------------------------------|---------|
| | Clone 1 | Clone 2 |
| Water | 4.26 | 3.75 |
| Supernatant | 3.83 | 0.84 |
| Arsenate extract of residue | 0 | 3.58 |
| Tissue residue | 0 | 0 |
| Residue after ten extractions with arsenate solution | 3.94 | |

activity of the primary supernatant (clone 2) or of the arsenate extract (clone 1) was thermolabile (Table 3). These solutions did not decrease in activity when dialysed against distilled water for 48 hr and were free from detectable proteolytic and adenosine triphosphatase activity.

Table 3 THERMOLABILITY OF THE SOLUBLE GLUTAMYLTRANSFERASE INHIBITOR OF CLONE 2 ROOTS

| Time (min) of exposure of inhibitor solution to 100° C | Glutamylhydroxamate (μ moles) |
|--|------------------------------------|
| 0 | 0 |
| 5 | 0.8 |
| 10 | 1.2 |
| 15 | 2.5 |
| 30 | 3.7 |
| 45 | 4.5 |
| 60 | 4.5 |
| Water control | 4.65 |

A purified preparation of the glutamyl-transferase enzyme was at this point obtained from 2 kgm dried pea meal (*Pisum sativum* var Meteor) by the method of Elliott⁷, dissolved in the *tris* buffer, and the sensitivity of both the transferase and the synthetase activities of the enzyme to the tomato root inhibitor tested. The standard reaction mixture (3.3 ml) used in assaying glutamine synthetase activity contained 0.5 ml 0.1 M *tris* buffer (pH 7.2), 1 ml enzyme solution, 0.5 ml sodium-adenosine triphosphate (0.05 M), 0.5 ml sodium glutamate (0.5 M), 0.1 ml manganese sulphate (M), 0.1 ml hydroxylamine (M) and adjusted to pH 7.2, and 0.1 ml cysteine (M). In these tests a partially purified preparation of the inhibitor was used. This was prepared from a clone 2 root homogenate (100 gm fresh wt roots to 200 ml water) as follows: the supernatant was treated with 300 ml acetone and the precipitate collected by centrifuging, washed with acetone and reduced to a dry powder in a vacuum desiccator. Half the acetone powder dissolved in 50 ml water was treated with an equal volume of saturated ammonium sulphate solution and the precipitate collected by centrifuging and dissolved in water. This solution was dialysed at 2–5° C for 48 hr and then adjusted to 50 ml. The preparation of an active acetone powder ensured inactivation of any glutaminase⁸ or adenosine triphosphatase⁹ contamination. The inhibition, by the purified inhibitor, of the transferase activity of the pea meal enzyme is shown in Table 4.

Inhibition of the transferase activity by the purified inhibitor was not reduced by addition of 0.05 M

Table 4 ATTEMPTED PURIFICATION OF THE GLUTAMYLTRANSFERASE INHIBITOR PRESENT IN EXTRACTED TOMATO ROOTS

| Inhibitor fraction | Dry wt inhibitor required to cause 50 per cent inhibition of transferase activity (μ gm) |
|--|---|
| 1 Original supernatant | 1,200 |
| 2 Acetone powder | 450 |
| 3 Dialysed ammonium sulphate precipitate | 76 |

cysteine or glutathione. Its inhibitory activity was maximal if incubated with the pea enzyme for 10 min before adding substrates and cofactors. Prolongation of this preincubation for 60 min, using an inhibitor addition causing about 50 per cent inhibition, did not lead to any further decrease in enzyme activity. The inhibition was only slightly reduced by increasing the concentrations of glutamine or adenosine triphosphate in the reaction mixture (Table 5). There was no evidence that the inhibitor reduced the effective concentrations of Mn^{++} , arsenate or hydroxylamine.

Table 5 EFFECTS OF L-GLUTAMINE AND ADENOSINE TRIPHOSPHATE CONCENTRATIONS UPON THE PERCENTAGE INHIBITION OF GLUTAMYLTRANSFERASE ACTIVITY BY THE PARTIALLY PURIFIED TOMATO ROOT INHIBITOR

| L-Glutamine (mM) | Glutamylhydroxamate formed (μ moles) | | Percentage inhibition |
|--------------------|---|-------------------|-----------------------|
| | Inhibitor omitted | Inhibitor present | |
| 4 | 2.4 | 1.14 | 53 |
| 8 | 4.0 | 2.2 | 45 |
| 12 | 5.7 | 3.4 | 41 |
| 20 | 8.1 | 4.95 | 39 |
| ATP (M) | | | |
| 10^{-3} | 0.0 | 0.24 | 60 |
| 4×10^{-3} | 2.1 | 0.90 | 57 |
| 10^{-4} | 3.4 | 1.5 | 55 |
| 4×10^{-4} | 3.8 | 1.0 | 50 |
| 10^{-5} | 3.0 | 1.0 | 47 |

The inhibitor was active against both the transferase and the synthetase activity of the pea meal enzyme (Table 6).

Table 6 ACTIVITY OF THE PARTIALLY PURIFIED INHIBITOR AGAINST THE TRANSFERASE AND SYNTHETASE ACTIVITIES OF THE PEA MEAL ENZYME

| Enzyme activity | Glutamylhydroxamate formed (μ moles) | | Percentage inhibition |
|-----------------------|---|-------------------|-----------------------|
| | Inhibitor omitted | Inhibitor present | |
| Glutamate-transferase | 4.70 | 1.03 | 78 |
| Glutamine synthetase | 0.31 | 2.77 | 56 |

Homogenates of seedling roots of pea (*Pisum sativum* var Meteor) also showed inhibitory activity, but it could not be detected in red clover roots (*Trifolium pratense* var Dorset Marigrass), and seedling roots of *Avena* (var Victory) showed high glutamate-transferase activity.

Acknowledgment is made to the University College of Swansea for a research fellowship and to the Indian Institute of Science for the leave of absence which enabled one of us (C. S. V.) to undertake this work, to Prof. H. Walsch of Columbia University for a pure sample of glutamylhydroxamic acid and to Imperial Chemical Industries, Ltd., for a grant towards the purchase of the Unicam spectrophotometer (SP 500) used in the estimation of the hydroxamic acid.

FORTHCOMING EVENTS

Monday, September 21

INSTITUTE OF METAL FINISHING (at the Northampton Polytechnic St John Street, London, E.C.1) at 6.15 p.m.—Mr A. O. N. Freund and Mr A. H. Barber: "The Use of Titanium in Electrolytic Processes for Metal Finishing"

Thursday, September 24

OIL AND COLOUR CHEMISTS ASSOCIATION (at Manson House 26 Portland Place, London, W.1) at 7 p.m.—Mr J. A. L. Hawley: "A Technologist's View of the Fourth Epoch"

Friday September 25

HOSPITAL PHYSICIANS ASSOCIATION (in the Lecture Theatre, Main Medical School, King's College Hospital, Denmark Hill, London, S.E.5) at 8.30 p.m.—Prof. D. G. Catchside, F.R.S.: "The Influence of Nutrition on Mutation Induced by Radication" (Sixth Douglas Lea Memorial Lecture)

Wednesday, September 30

BRITISH INSTITUTE OF RADIO ENGINEERS (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1) at 8.30 p.m.—Mr W. E. Williams: "Modern Microwave Valves—a Survey of Evolution Principles of Operation and Basic Characteristics"

Thursday October 1—Friday October 2

INSTITUTE OF BIOLOGY (in the Lecture Hall, Royal Geographical Society Kensington Gore, London, S.W.7) at 10 a.m. daily—Symposium on "Biological Problems Arising from the Control of Pests and Diseases"

SOCIETY OF CHEMICAL INDUSTRY FOOD GROUP (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1)—Symposium on "Enzymes in the Manufacture, Storage and Distribution of Food"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

RESEARCH ASSISTANT (preferably graduate in mathematics and physics) to assist in the design of digital computers in the Computing Laboratory to assemble and run programmes using the Interpretative schemes in the Deuce Computer—The Secretary of University Court, The University, Glasgow (September 28)

ASSISTANT LECTURER IN BOTANY—The Registrar, The University, Manchester 13 (September 30)

TECHNICAL ASSISTANT (qualified to maintain and supervise the use of X-ray apparatus and the electron microscope) in the HOLDSWORTH SCHOOL OF APPLIED SCIENCE—The Registrar, The University, Leeds (September 30)

LECTURER IN PHYSIOLOGY—The Secretary, The University, 38 North Bailey, Durham (October 1)

LECTURER IN THE HISTORY OF SCIENCE—The Registrar, The University, Leicester (October 1)

RESEARCH ASSISTANT (graduate) in the DEPARTMENT OF AGRICULTURE to carry out investigation into the efficiency of farm buildings by the application of work study methods—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (October 1)

LECTURER OR SENIOR LECTURER IN PHYSICS AND/OR CHEMISTRY to take subject to First Degree standard—The Principal, Biele College, Durham (October 3)

READER OR SENIOR LECTURER (with experience in experimental physics and preferably experience in some aspects of applied physics) in the DEPARTMENT OF PHYSICS in the School of Science—The Registrar, The University, Manchester 13 (October 5)

LECTURER (with special qualifications in hydrography) in **OGROGRAPHY**—The Registrar (Room 22, O.H.N.), The University, Reading (October 10)

CHAIR OF PHYSICS, CHAIR OF CHEMISTRY, AND CHAIR OF BIOLOGY in the University of Malia—The Secretary, Inter University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15)

LECTURER OR ASSISTANT LECTURER IN BACTERIOLOGY at the University of Malia (Singapore Division)—The Secretary, Inter University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15)

LECTURER (with a qualification in biochemistry and preferably with a medical qualification) in **CHEMICAL PATHOLOGY**—The Dean, St Thomas' Hospital Medical School, London, S.E.1 (October 16)

LECTURER OR ASSISTANT LECTURER IN PHYSICS at **SIKARENE COLLEGE** (University College of East Africa)—The Secretary, Inter University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 20)

LECTURER IN MICROBIOLOGY in the Faculty of Rural Science, University of New Zealand, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 23)

LECTURER IN NUTRITION in the Faculty of Rural Science, University of New Zealand, Australia, to undertake teaching and research in livestock nutrition in the Department of Nutrition and Chemical Pathology—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 23)

LECTURER, SENIOR LECTURER OR ASSOCIATE PROFESSOR IN APPLIED CHEMISTRY at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 23)

SENIOR LECTURER (preferably with research experience in the field of neurophysiology) in **PATHOLOGY** at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 24)

CHAIR OF BOTANY—The Secretary, The Queen's University Belfast (October 31)

CHAIR OF INORGANIC AND PHYSICAL CHEMISTRY in the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31)

DEMONSTRATORS IN BIOCHEMISTRY, ANIMAL OR PLANT PHYSIOLOGY, SOILS, PARASITOLOGY, LIVESTOCK ANATOMY AND HISTOLOGY, VETERINARY AGRICULTURE, LIVESTOCK HYGIENE AND PATHOLOGY—The Registrar, University of New England, Armidale, N.S.W. Australia (October 31)

SENIOR RESEARCH FELLOW OR RESEARCH FELLOW IN THE DEPARTMENT OF THEORETICAL PHYSICS, Research School of Physical Sciences, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 2)

LECTURER (with qualifications in either pure or applied mathematics) in **MATHEMATICS** at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 30)

ASSISTANT OR ASSOCIATE PROFESSOR OF PATHOLOGY at Queen's University, Kingston, Canada—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1

LECTURER IN MATHEMATICS—The Secretary, Royal College of Science and Technology, Glasgow

RESEARCH ASSISTANTS (graduates) in ELECTRICAL ENGINEERING for work in the fields of transistor applications or the properties of dielectric materials—Head of the Electrical Engineering Department, Northampton College of Advanced Technology, St John Street, London, E.C.1

RESEARCH ASSISTANTS (2) IN PHYSICS one for theoretical and/or experimental work connected with the theory of liquids and the other for meteorological or solid state physics—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3

SENIOR TECHNICAL OFFICER (with a degree or diploma in agriculture or agricultural botany) in the CEREALS SECTION of the Seed Production Branch—The Secretary, National Institute of Agricultural Botany, Huntingford Road, Cambridge

ASTROPHYSICS

Magnetic Field Associated with a Great Solar Flare

An unusually large solar flare of intensity 3+ was observed at Mount Wilson on July 16 1959. The flare was in an active region centered on the spot group at approximately 18°N 20°W. It showed a predominantly S-shaped or double spiral configuration, with marked variations of relative intensity in its various parts. Visual observations of the spectrum showed that the flare commenced abruptly between 21 19 and 21 24 UT, maximum was between 22 01 and 22 13 UT. Lines of Ca II, Na I_o and H were observed to be in emission for more than 1 hr; the width of the H α emission was greater than 6 Å. Emission persisted in the lines of Ca II and of H until after observations were terminated at 01 00 UT on July 17.

Beginning at 21 37 UT observations were made at intervals of a few minutes with the solar magnetograph modified for fine scanning, and with the spectroheliograph 14 fine scan magnetograms of hydrogen spectroheliograms and 49 spectroheliograms of the flare region were obtained during the 3½ hr of observation.

To require data on the detailed variations of the photospheric magnetic field during the progress of flares, the solar magnetograph¹ had been extensively modified, making it possible to scan a limited region of the Sun's disk 4.5 min of arc square, with a resolution of 5 sec. The scanning is carried out automatically with conformal recording on a cathode ray tube fitted with a camera. The recording spot is drawn out into a short line which is made to slant either to the right or to the left to indicate the magnetic polarity. Intensity of the component of the field in the line of sight is indicated by means of intensity modulation of the trace, changing abruptly at levels corresponding to 5, 10, 20 and 40 gauss. Thus, each magnetogram is a magnetic map showing the location, polarity and intensity of the detailed magnetic field. With the fine scan equipment sequences of such magnetograms can be produced at the rate of four per hour in order to show changes. Although at the time of these observations the apparatus had not been fully perfected in all technical details, it provided valuable data.

A comparison of the 14 fine scan magnetograms shows no definite change in the magnetic pattern. Thus these observations provide no evidence that the occurrence of the flare led to the destruction or radical redistribution of the magnetic field. This is not surprising, since the flare is a chromospheric phenomenon occurring at a higher level than the photosphere, to which the magnetic observations pertain. Large variations in the magnetic field pattern of the photosphere in a few hours would entail material velocities much greater than those normally observed in the photosphere. High velocities in the chromosphere are of course not excluded.

Four small flares have been observed since the large flare of July 16. For all these there are fine scan magnetic observations before, during and after the flares. In no instance was a change in the field apparent.

Solar Effects in the Motion of Vanguard

A NEW analysis which I have carried out of the complicated period changes of Satellite 1958 g₂ (*Vanguard*) shows a correlation with three solar effects: (1) the hour angle of the Sun as reckoned from the perigee point of the orbit, (2) the 27 day variations in solar activity discovered by Jacek¹, (3) the total daily solar insolation at the latitude of perigee.

The major atmospheric drag is well known to occur at or very near the perigee point of the elliptical orbit of a satellite, and the observed rate of decrease of period is proportional to the Satellite's area/mass ratio, the air density at perigee and the square root of the atmospheric scale height at perigee. Data on the period changes of *Vanguard* are very precise, but nevertheless they show a highly complex periodic variation with time. The dominant variation of the drag of *Vanguard* correlates with the hour angle of the Sun as measured from perigee. A diurnal effect appears to have been first noticed by Jacek¹. In the early days of *Vanguard* in the spring of 1958 the local solar time at perigee was 7 00 or 8 00 a.m. and the average weekly decrease in orbital was only about 0.002 min. Because the perigee advances 4.4 deg per day and the node regresses 3.0 deg per day, the right ascension of perigee on the average advances 1.4 deg per day as compared with 1.0 deg per day for the Sun. Thus the length of the 'day' at *Vanguard*'s perigee is 360°/0.4° days or 2.5 years. During August, September and early October of 1958 the weekly period change increased markedly as the local time at perigee increased from 10 30 a.m. to 1 30 p.m., reaching a peak in October of about 0.007 min. Since then the average change has decreased slowly but steadily to a minimum of only 0.001 min in July 1959, when the local solar time at perigee was 8 00 p.m. Table I gives values of the average weekly period decrease as a function of the solar hour angle at perigee. Entries are the ratios of observed period decreases to the average weekly period decrease over the history of the orbit through July, 1959 (-0.0032 min/week).

Table 1 RELATIVE RATE OF PERIOD DECREASE AS A FUNCTION OF THE HOUR ANGLE OF THE SUN RECKONED FROM PERIGEE

| Hour angle (deg) | 300 | 320 | 340 | 0 | 20 | 40 | 60 | 80 | 100 | 120 |
|---------------------|------|------|------|------|------|------|------|------|------|------|
| Period decrease | 0.65 | 0.58 | 0.67 | 1.31 | 1.93 | 1.57 | 1.36 | 1.13 | 0.70 | 0.32 |

It appears that this correlation of drag with time of day at perigee passage can be accounted for either by a daily expansion and contraction of the exosphere or by a daily variation of ionization in the exosphere. The latter effect will, in accordance with the ideas of Jastrow and Pearce³, result in charged drag, in which the effective cross-sectional area of the satellite is increased. If, however, the maximum admissible electron density in the exosphere is $2 \times 10^5 \text{ cm}^{-3}$, as pointed out by Spitzer⁴, then charged drag is negligible as compared with neutral drag. In my own view the interpretation of this effect as oscillations of the exosphere is to be preferred. If the outer atmosphere pulsates daily, the observed minimum drag of *Vanguard* is consistent with locating the base of the exosphere at 600 km and ascribing to it a scale-height of 100 km and density $9 \times 10^{-13} \text{ gm/cm}^3$, whereas the observed maximum at local time about 130 p.m., suggests that the base has moved up to about 800 km with scale-height 120 km and density $8 \times 10^{-13} \text{ gm/cm}^3$. These figures imply typical vertical winds of some 30 km/hr at the level of *Vanguard's* perigee and greater speeds farther aloft. The time of maximum drag, and hence maximum density and temperature, corresponds roughly with the hour of maximum heat at the Earth's surface and also with the hour of maximum ionisation in the ionosphere.

Superposed on this effect are the 27-day variations in drag due to solar activity, found by Jacchia¹. The decrements in weekly period fluctuate strikingly in phase with the sunspot number, the amplitude of the fluctuations averages 25 or 30 per cent of the mean rate of period decrease.

The third periodic effect is a seasonal one. Since the perigee of *Vanguard* advances at the rate of 4.4 deg per day, it migrates between latitudes 34° N and 34° S , completing a full cycle every 82 days. The total daily insolation at the latitude of perigee stands normally at a high tropical level. In terms of the insolation at the equator on the equinoxes at Earth's mean distance, the equatorial insolation ranges between 0.89 and 1.01, while at latitude 34° it never exceeds 1.18. However at the winter solstices at latitude 34° it dips to 0.46 in the northern hemisphere and 0.43 in the southern. When the hour-angle and solar-activity effects are removed, the residual weekly period decrease is less than normal on the several occasions when perigee has reached maximum latitude on or near the time of the winter solstice. The effect is rather weak in the northern hemisphere, but well marked in the southern. When perigee reached latitude 34° S on July 9, 1958 and again on June 9, 1959, the period decrease was reduced for a couple of weeks to about 50 per cent of neighbouring values, and on September 29, 1958, to about 60 per cent. Although still uncertain, the correlation of this third effect with seasonal insolation is somewhat improved when compared with the insolation some six weeks before the date in question, implying that the exospheric seasons lag in more or less the same way as the surface seasons.

Although the data are not so precise, *Satellite 1958 α (Explorer I)* seems to behave in the same fashion as *Vanguard* with respect to these three effects.

This work was supported by the National Science Foundation under Grant Y32 40/266, with Prof G W Swenson, jun, as principal investigator.

PHYSICS

Propagation of Ultrasonic Waves in Liquids

PREVIOUS measurements of the heat produced by ultrasonic waves in a trap vessel¹ gave results that differed from those obtained by other methods² for the absorption coefficients in carbon disulphide, xylene and kerosene, the last two appear to have abnormally high values, particularly from measurements with narrow trap vessels. The results were confirmed with trap vessels made of plaster of Paris, with windows of thin paper or 'Cellophane' in place of mica. The abnormal behaviour cannot, therefore, be attributed to any electrical effect in the metallic core of the trap, or to the mica windows.

With the view of elucidating these observations, the steady heat developed in a trap vessel, placed 15 cm from a quartz crystal oscillator, was measured with extra partitions in front. With single partitions at 2 cm or 12 cm, or with partitions at both 2 cm and 12 cm, the heat dissipated in kerosene was reduced by 15, 40 and 80 per cent respectively. Insertion of a diaphragm close to the quartz might be expected to reduce the measured energy by a large amount, due to scattering or reflexion. The results obtained are, therefore, not easily explicable.

It was considered necessary to measure the energy behind one or more partitions directly. For this purpose, the deflexions of a double 'Cellophane' disk and of a single 'Cellophane' disk respectively, suspended in an ultrasonic beam, were measured with a travelling microscope. The disks were suspended from a supporting rod, in a closed glass chamber, by unspun silk threads 50 cm long. The rod could be moved longitudinally and transversely by screws. The deflexion of the single disk measured the flow energy, with a limiting value of about 15 per cent of the total energy due to the frame size. The double 'Cellophane' disk measured the total energy.

Measurements of deflexions of the two disks, suspended in benzene or kerosene, were made at two distances from the quartz crystal, and the absorption coefficients were calculated. The value obtained for benzene was in good agreement with those obtained by other methods. The absorption coefficient of kerosene was also measured at positions near the quartz crystal, and immediately behind the mica window. The values were much higher than those normally obtained (Table 1). This explains the large absorption in a narrow trap vessel placed near the quartz, observed earlier¹.

* Power adjusted for different sets

Deflexion measurements were also made with a varying number of partitions in front of the disk (Table 1). The constant intensity of a fairly high percentage, obtained by the insertion of three or four partitions indicates that the ultrasonic radiation passing through three partitions is not affected by the fourth one. The gradually decreasing reductions in energy intensity produced by the first three partitions, together with full transmission by the fourth suggest that vibrations propagated in the liquid are affected differently by the partitions. Some are easily dissipated, whereas others forming a homogeneous group are not affected by the partitions.

From the results in Table 1 benzene appears to absorb a larger percentage of easily dissipated energy. A larger reduction, obtained at higher frequencies (not tabulated) shows that the inhomogeneous group increases with frequency. Observations with two sets of mica partitions, one near the quartz crystal and the other in front of the disk, farther from the quartz, indicate since it has the same effect as the first set, that the inhomogeneity is created in the liquid. The previous observations on heat measurements with a trap vessel and extra partitions are now understandable. The values have also been confirmed by deflexion measurements with a similar arrangement of the partitions.

The nature of the inhomogeneity of the group of rays was ascertained from a study of the number and character of diffraction spectral lines. The spectrum produced by an inhomogeneous ultrasonic beam was noted both when it was unobstructed and when it was reduced by three mica partitions to a homogeneous group with 50 per cent of the former strength. The spectrum for the unobstructed source reduced to 50 per cent of the former strength by a reduction of the input wattage was also noted. The observed numbers of fringes were seven and five respectively determined only by the ultrasonic intensity irrespective of the group character. The

homogeneous group however gave sharp fringes. The comparative numbers of the fringes for the two intensities agree well with Sander's¹ relation $n^2 \propto$ wattage. Apparently the homogeneous and the inhomogeneous groups of rays have only a small variation in wave length, and thus contribute equally to the formation of any spectral order with a small spread. Large variations give rise to dissipation. Such a mechanism had been suggested previously by one of us (A. K. D.)²

The measurements throw some light on the origin of flow energy for which various mechanisms have been suggested.³ Table 1 shows some significant comparative values of the flow energy percentage. (1) The flow energy percentage falls rapidly as the number of partitions is increased. (2) The percentage of flow energy is comparatively large in the following cases: (a) in benzene compared to kerosene, (b) close to, as compared to far from the quartz (c) immediately behind, as compared to far from, a mica partition. All these observations suggest that the flow associated with the vibratory energy is directly related to the associated inhomogeneous group of rays present after strong absorption and that it appears only when there is a superposition of these wave groups. This is in agreement with the requirement deduced by Nyborg.⁴

The Flow of Blood through Narrow Tubes

IN a recent letter, one of us¹ has shown that the flow of the blood of several species in a single capillary tube of radius R and length L follows an equation recently proposed by Casson² for varnishes and inks

$$\left(\frac{PR}{2L}\right)^{1/2} = k_0 + k_1 \left(\frac{4V}{\pi R^3}\right)^{1/2} \quad (1)$$

where P is pressure, V is volume flow/sec, k_0 and k_1 are constants. When k_0 becomes zero, this equation reduces to the well-known equation of Poiseuille, since the terms in parenthesis represent the stress and shear rate respectively, at the wall of the tube. When k_0 has finite values, however, it is a measure of a yield-value or critical shearing stress which, as pressure is raised, will be first reached at the capillary wall. As pressure still further increases, the critical distance (r_0) from the centre at which this occurs, will steadily diminish. A similar phenomenon was studied many years ago for the Bingham equation, which differs from Casson's equation only in the absence of square roots, when Buckingham³ and, independently, Reiner⁴ evaluated the correct equation of flow for such a system

$$V = \frac{\pi R^4}{8k_1^2 L} \left(P - \frac{4}{3}p + \frac{p^3}{P^2} \right) \quad (2)$$

where p is the pressure corresponding to the yield-value given by $p = 2Lk_0^2/R$.

In the present communication a similar treatment is applied to Casson's equation since, like Bingham's equation, a correction to allow for the changing value of r_0 with increasing pressure must be made if a linear relation is to be obtained.

Re-writing equation (1)

$$k_1 D^{1/2} = \tau^{1/2} - k_0 \quad (3)$$

where τ is the shear stress (absolute value). Integration gives

$$k_1^2 v = \frac{r\tau}{2} - \frac{4}{3}r^{-1/2} k_0 + r k_0^2 + C$$

where v is the velocity of flow at distance r from the centre of the tube. If the material adheres to the wall, $v = 0$ when $r = R$, from which the integration constant C can be calculated

Fig. 1

Introducing τ_R for the shear stress at the wall

$$V = \int_0^R r^2 dv = \frac{\pi R^3}{4} \tau_R \left[1 - \frac{16}{7} \frac{k_0}{\tau_R^{1/2}} + \frac{4}{3} \frac{k_0^2}{\tau_R} - \frac{1}{21} \frac{k_0^4}{\tau_R^3} \right] \quad (4)$$

This replaces the original Buckingham equation (2). $k_0/\tau_R^{1/2}$ is small this approximates to

$$V = \frac{\pi R^3}{4} \tau_R \left[1 - \frac{8}{7} \frac{k_0}{\tau_R^{1/2}} \right]^2$$

or

$$\left(\frac{4V}{\pi R^3}\right)^{1/2} = \frac{1}{k_1} \left(\tau_R^{1/2} - \frac{8}{7} k_0 \right)$$

Thus if $\left(\frac{4V}{\pi R^3}\right)^{1/2}$ is plotted against $\tau_R^{1/2}$, a straight line is obtained, from which k_1 and k_0 can be determined as shown in Fig. 1

Substrate Damage in Film Thickness Measurement by Beam Interferometry

IN the Tolansky method for the measurement of the thickness of thin films by multiple beam interference we have used a narrow channel in the film rather than a sharp step¹. The channel can be formed by gently drawing a needle across the film before the deposition of the reflecting over-layer. The technique is easily applied and has several advantages especially when the substrate is not optically flat as in the case of microscope slides.

Weaver and Benjamin² have recently directed attention to a possible source of error in the technique.

They report that in order to form clear channels through films, deformations of the glass substrate by the needle can occur. For chromium films they measured deformations amounting to several hundred angstroms. Unfortunately no indication was given as to the nature and shape of the deformation.

We have found that while it is certainly possible to mar the glass with a steel needle, any damage can be detected by the irregularities in the shape of the fringe. Hence appreciable errors in thickness arising from damage to the substrate can be avoided.

Dr Weaver kindly sent us some of the gramophone needles which they use, and we have compared the scratches made by these needles with the scratches made by the sewing needles which we often employ. The results are shown in Fig. 1, which illustrates fringes at a low order of interference³. Fringes (a) are from scratches through a film made with a sewing needle held at about 45° to the direction of motion. From (i) to (iv) the loads increase in the range 5–200 gm. Fringes (b i–iv) are from scratches made with a steel gramophone needle. It is evident that

Fig. 1 Multiple interference fringes of scratches made by steel needles through a thin metal film on a glass substrate: (a) with a sewing needle; (b) with a gramophone needle. Loads on the needle increase from (i) to (iv) in each case.

the gramophone needle is considerably harder than the sewing needle. The effect of a plastic deformation is clearly seen in the smooth build up on either side of the channel fringes (b ii) and (b iv). The deformation seen in Fig. (b iv) is very similar to the furrow given by a glass cutting diamond. With the sewing needle the damage is often irregular along the length of the scratch and appears to represent a removal of the glass. Since the substrate on either side of the channel remains plane even at high loads as at (a, iv) it is concluded that there is no plastic deformation of the glass.

Measurement of the hardness of the two kinds of needles showed that the gramophone needles are indeed considerably harder. The sewing needles always show a slight flattening at the point after having been drawn across the glass whereas the gramophone needles do not show any significant deformation. It is our opinion that the softer sewing needles produce a clear channel through a film because the point yields and flattens before marring the glass. No difficulty has been experienced in producing clear channels without substrate damage even in the case of the more strongly adhering films of copper or chromium. On the other hand the gramophone needle probably makes only irregular small area contact and even at light loads will damage the glass before voiding.

Because the multiple beam interference method especially at low orders is capable of detecting distances of one or two angstrom units and because the shape of the fringe is an excellent guide to possible substrate damage, the problem of deformation of the substrate does not introduce any significant error in the measurement of film thickness.

Some Semiconductive Properties of Dilute Binary Solid Solutions of Bismuth in Tellurium and Tellurium in Bismuth

IN connexion with my previous remarks on the bismuth-tellurium photo-voltaic sandwich layer¹ it has been of interest to investigate the presence of semiconductive properties of bismuth and tellurium alone, as well as of the binary solid solutions of bismuth in tellurium and tellurium in bismuth.

Bismuth and tellurium obtained from the American Smelting and Refining Co. of New Jersey will be designated in this communication as pure with a star, thus pure*. The spectroscopic analysis indicated the following information regarding the purity of these materials:

Bismuth contained 99.999 per cent bismuth, 0.0002 per cent silver, 0.0002 per cent lead, 0.0002 per cent copper, 0.0001 per cent iron and 0.0003 per cent unidentified impurities.

Tellurium contained 99.999 per cent tellurium and very faint traces of iron and copper.

Samples of bismuth-tellurium dilute binary solutions were obtained by melting and mixing the desired amounts of bismuth and tellurium pure* *in vacuo* at about 10^{-3} mm. mercury, and rapidly cooling down the envelope containing the melt. The container was then broken and the material tested with a hot probe for the type of conductivity. A few mgm. of the above material were then crushed into powder introduced into a Vacor tube and sealed to a vacuum system. After evacuating the tube to the pressure of 10^{-3} mm. mercury the powder was condensed on to the surface of a glass plate. The thickness of the layer amounted to about 1μ .

The type of conductivity was determined with a hot probe. It was then determined whether the film possesses the photo-voltaic property. A beam of radiation originating either from a tungsten lamp or from a soldering iron chopped at a frequency of 800 cycles/sec. and incident on the film produced electrical impulses which were amplified with a narrow band amplifier. The magnitude of the impulses was measured either by an oscilloscope or a vacuum tube voltmeter.

Bismuth. Bismuth is a semiconductor with bands which can be separated into slightly overlapping valence and conduction bands*. According to Aubrey and Chambers² the overlap between bands of holes and electrons is 0.018 eV and there are 0.86×10^{-3} electrons and holes in bismuth at 4°K . According to Heino³ there are 1.5×10^3 electrons and holes in bismuth. If donor atoms (tellurium) are added to bismuth the extra electrons go to fill up the band of holes. At concentrations of donors greater than 0.0015 per cent per atom there are no holes left and all further electrons go into the electron band. Is bismuth a photoconductive material? The work of Weber and Friederich⁴ does not prove that it possesses the property of photoconductivity in the modern meaning of the word. The abstract of Drummond⁵ which I came across during the preparation of this manuscript, does not give any information as to the purity of the material and due to its brevity it can only be assumed that the author deals with photoconductivity.

* Scott G. D., McLaughlin T. A. and Bennett R. S. *J. Appl. Phys.* 21, 843 (1950).

* Weaver C. and Benjamin P. *Nature* 182, 1149 (1958).

* Scott G. D. *J. Opt. Soc. Amer.* 48, 843 (1958).

I have performed some experiments on bismuth samples prepared by methods described here. The results are given in Table 1.

Table 1

| Bulk | | | | |
|--|-----------|-----------------------|---------------------|----------------------|
| | Bi pure* | Bi pure* + 0 1% Te | Bi pure* + 1% Te | Bi pure* + 10% Te |
| Thermo electric power in micro- volts per deg C | 50 ± 10 % | 30 ± 10 % | 25 ± 10 % | 20 ± 10 % |
| Type of con- ductivity | " | " | " | " |
| Conductivity in (ohm cm) ⁻¹ | | From 250 to 300 | | |
| Film | | | | |
| | Bi pure* | Bi pure* + 0 1% Te | Bi pure* + 1% Te | Bi pure* + 10% Te |
| Thermo-electric power in micro- volts per deg C | | From 10 to 50 | | |
| Type of con- ductivity | " | " | " | " |
| Conductivity in (ohm cm) ⁻¹ | | From 0.74 to 5 | | |
| Photo E M F in microvolts per 8 × 10 ⁻⁴ watt per mm square of incident radiation | | From 10 to 2 | | |

It is worth while mentioning that a few films of pure* bismuth were evaporated in an atmosphere of air at pressures 75, 15 and 1 μ mercury. Only the last one was found to be sensitive, its output being several microvolts E M F when illuminated.

Tellurium Tellurium is a semiconductor.² According to Loferski³ the optical band gaps are 0.32 eV and 0.37 eV for lights polarized normally to and in parallel with the c axis respectively.

Kronmüller, Jaumann and Seiler⁴ obtained very pure tellurium by distillation and sublimation, and then doped it with arsenic, antimony, bromine and iodine. In all cases the extrinsic tellurium was p type. Moss⁵ prepared a film about 10⁻⁴ cm thick which had considerable photoconductive sensitivity to infra-red at 90° K.

Table 2

| Bulk | | | |
|--|--|---------------------------|----------------------------|
| | Te pure* + | Te pure* + 1% Bi (atomic) | Te pure* + 10% Bi (atomic) |
| Thermo-electric power in microvolts per deg C | 360 ± 10% | 110 ± 10% | 50 ± 10% |
| Type of conductivity | p | p | p |
| Conductivity in (ohm cm) ⁻¹ | 20 ± 10% | 500 ± 10% | 750 ± 10% |
| Film | | | |
| | Te pure* | Te pure* + 1% Bi (atomic) | Te pure* + 10% Te (atomic) |
| Conductivity in (ohm cm) ⁻¹ | About 1 000 times smaller than for bulk material | | |
| Photo E M F in microvolts per 8 × 10 ⁻⁴ watts per mm square of incident radiation | From 30 to 10 | | |

I have prepared a number of samples by the method described above, and carried out some measurements, the results of which are shown in Table 2.

On the basis of the information just presented it seems reasonable to assume that the dilute binary solutions of bismuth-tellurium are semiconductors.

One can also expect that bismuth-tellurium solutions in all other proportions are semiconductive materials.

It was shown by Vasenin¹⁰ and by Haken¹¹ that both the sign and the magnitude of the thermo electric power of bismuth-tellurium solutions depend on the ratio of bismuth to tellurium. The thermo electric power changes sign with respect to copper five times over the range of composition, assuming three maxima and three minima.

It seems thus worth trying to evaporate on to the surface of a glass or quartz plate first a layer of a certain composition of bismuth-tellurium and on the top of it another layer of selected composition with a view of obtaining the best possible characteristic of a p-n junction. Another possibility is to try to realize a p-n-p or n-p-n layer and look for a transistor effect.

As a unit cell of Bi₂Te₃ consists of alternate layers of bismuth and tellurium it is possible that thin-film techniques could be used to investigate the properties of bismuth-telluride.

METALLURGY

Dislocation Arrangements in Molybdenum

RECENTLY, several studies of dislocations in face centred cubic metals by the method of transmission electron microscopy have been reported. Of the body-centred cubic metals, however, only iron has so far received attention^{1,2}. In this letter we give a preliminary account of some experiments on dislocation movements during deformation and recovery processes in molybdenum.

The starting material was a 0.0005 in thick cross rolled molybdenum foil of 99.90 per cent purity supplied by Messrs Metro-Cutani. Further thinning was achieved by electrolytic polishing in a solution of 25 per cent sulphuric acid in methanol using a technique similar to that described by Bollmann³ but with a cylindrical nickel sheath replacing the stainless steel point cathodes. An applied potential of 2 volts with a current density of about 20 mA cm⁻² were found to be satisfactory and required a polishing time of about 15 min. The specimens were examined in a Siemens Elmiskop 1 microscope operated at 80 kV.

Fig 1a shows a sub grain boundary in a specimen prepared from the as rolled foil. The dislocation density within the sub grains is surprisingly low and it is not yet clear whether this is due to low temperature recovery processes or whether the electrolytic thinning technique is selecting regions of the specimen that are not typical of the whole. So far neither dislocation loops nor dislocation pile ups have been observed.

Specimens which were annealed at a high temperature before electrolytic thinning have also been studied. Fig 1b shows a specimen which was annealed for 1 hr at 1,400°C in vacuum. The dislocations have formed up into a tangled network similar to those already observed in iron. An intermediate stage in the formation of networks is shown in Fig 1c which shows a specimen annealed for 1 hr at 950°C. In this case some of the dislocations have a characteristic zig zag shape suggesting that they have started to move but have been pinned down at various points along their lengths presumably by impurity atoms.

This work is being extended to include a study of deformation processes in fully annealed specimens and also the effects of neutron irradiation damage.

Fig 1. a. A sub-boundary in a rolled and electrolytically thinned molybdenum foil ($\times 77,000$). b. Dislocation networks in molybdenum formed by annealing a rolled foil for 1 hr at 1,400°C in vacuum ($\times 67,000$). c. Zig zag dislocations in a specimen which was annealed for 1 hr at 950°C in vacuum after rolling ($\times 60,000$).

We are indebted to Prof J. G. Ball for his advice and encouragement, to the Central Electricity Generating Board for a research bursary (J. F. K.) and the ICI Research Fellowships Committee of the University of London for the award of an ICI Fellowship (A. A. J.).

CHEMISTRY

'Eddy' Diffusion in Chromatography

Among the various diffusion and kinetic factors which are responsible for smearing chromatographic zones, the effect known as 'eddy' diffusion has been subject to the most controversy. Its contribution to the height equivalent to a theoretical plate (H) is usually assumed to depend only upon the packing of a column and to be independent of the velocity of flow. This assumption may be questioned by virtue of recent experimental work in chromatography.¹⁻³ An equation will be derived here which predicts 'eddy' diffusion to be dependent on velocity. This will be compared to the existing experimental evidence.

The mathematical difficulties connected with a rigorous treatment of flow in porous media make an approximate theory necessary. While the theory outlined is perhaps over-simplified, it is doubtful if significant gain could be made short of a rigorous solution. Beran⁴ has approached the problem rigorously, but did not arrive at my principle result (equation 7).

'Eddy' diffusion is due to the irregularity of stream paths in a porous medium.⁵ The velocity along a given stream line will persist for a distance of the order of d_p (particle diameter), after which a new velocity differing by about v (the average velocity) from the original will be randomly acquired. The process is analogous to a random walk or flight, in which molecules within the stream paths stop back and forward with respect to the average velocity.

In addition to the velocity fluctuations within a stream path, a molecule is able to alter its velocity by diffusing laterally nearby stream paths. Such an effect is found with capillary columns.⁶ The combined influence of velocity fluctuations due to following and due to crossing stream lines will now be established.

The diffusion coefficient due to the above processes assumed as a random walk is:

$$D = \frac{l^2 n}{2} = \frac{v^2}{2n} \quad (1)$$

where the length of step, l , is the average distance travelled in 1 sec divided by the number, n , of steps per sec, $l = v/n$. The number, n , is the sum of the number due to the two independent processes mentioned above. In the first instance we assume that a stream path must proceed a distance $2d_p$ to complete a step.

$$n_1 = \frac{v}{2d_p} \quad (2)$$

In the second instance we assume that diffusion must take a molecule the distance βd_p to complete a step. The values of λ and β are expected to be of the order of unity, while changing slightly with a change in packing.

¹ D. G. Brundage and J. N. Pittling, *Adv. Mol. Sci.*, 7, 101 (1959).

² M. E. Lean, reported by N. P. Allen, *J. Iron and Steel Inst.*, 191 (1959).

³ W. Follman, *Phys. Rev.*, 103, 1588 (1956).

$$n_2 = \frac{2D_I}{\beta^2 d_p^2} \quad (3)$$

The diffusion coefficient of solute molecules in the mobile phase is D_I . Using the expression $n = n_1 + n_2$ in equation (1) we obtain

$$D = \frac{v^2}{v/\lambda d_p + 4D_I/\beta^2 d_p^2} \quad (4)$$

If the molecule is retained by adsorption or desorption during a fraction $(1 - R)$ of the time, D is correspondingly reduced. The value of H in terms of D is $H = 2D/Rv$. The expression for H is consequently found as

$$H = \frac{2\lambda d_p}{1 + 4D_I/\beta^2 d_p^2} \quad (5)$$

This, of course, is the contribution to H due only to these effects. The full expression for H also has a contribution from ordinary molecular diffusion and kinetic effects. In Fig. 1 H is plotted as a function of v . At the velocity $v_{1/2} = 4\lambda D_I/\beta^2 d_p$, H is one-half its maximum value.

At low velocities of flow, H becomes proportional to the velocity. This limiting value of H is identical in form with that obtained by Golay⁶ for capillary columns. It is exactly equal if we let $\beta d_p = r_0/\sqrt{12}$, where r_0 is the radius of the capillary. This fact may be of some use in estimating β . At high velocities $H = 2\lambda d_p$ and is independent of velocity. This expression is identical with that used in the van Deemter equation for 'eddy' diffusion. In gas chromatography, where the greatest refinements have been made, the transition velocity $v_{1/2}$ will be somewhere in the neighbourhood of 10–100 cm/sec. This is assuming $4D_I/\beta^2 = 10$, $D_I = 0.1$ cm²/sec and $d_p = 0.05$ cm. Due to the approximations, the result 10–100 cm/sec must be regarded only as an indication of where to look for the transition. This velocity, of course, is in the range where the performance of most columns is an optimum.

Fig. 1 Variation of theoretical plate height with velocity

Evidence which bears on these effects is indirect and not conclusive. Glueckauf³, assuming $H = 2\lambda d_p$, plotted λ versus velocity of flow for radioactive hydrogen iodide washed by an acidified solution over glass beads of diameter about 0.05 cm. The ordinate and abscissa of his graph vary only by a scale factor from Fig. 1. The two graphs are similar, with a rapid drop at low velocities. The values of $v_{1/2}$ estimated from these curves are of the correct order, assuming $D_I = 10^{-5}$ cm²/sec. In a later experiment⁷, in which krypton-85 was eluted with hydrogen, methane, oxygen and sulphur dioxide, no evidence was found for a variation of 'eddy' diffusion. However, if my equation 5 is substituted for A , curves are obtained which bend slightly away from the $1/v$ axis. The results presented seem to confirm this trend.

An anomalous result concerning 'eddy' diffusion was reported by Bohemen and Purnell.¹ The 'eddy' diffusion term was found to be negative in a number of cases, notably those with small particle size down to about 0.01 cm. This result would be found if one were in the low-velocity domain, and further, one is shifted towards this condition by smaller particle sizes.

In a different experiment performed by Bohemen and Purnell, hydrogen and nitrogen were compared as carrier gases. If 'eddy' diffusion were constant, the difference in plate height, $H_{H_2} - H_{N_2}$, would be described by an equation which allows only for molecular diffusion.

$$\Delta H = H_{H_2} - H_{N_2} = \frac{a}{v} (D_{H_2} - D_{N_2}) \quad (6)$$

plotting experimental values of ΔH against $1/v$ yielded a curved line intercepting the $1/v$ axis rather than a straight line through the origin. If it were assumed that the low-velocity form of equation 5 is valid, the equation for ΔH should read

$$\Delta H = \frac{a}{v} (D_{H_2} - D_{N_2}) + bv \left(\frac{1}{D_{H_2}} - \frac{1}{D_{N_2}} \right) \quad (7)$$

This equation does yield a line curved into the $1/v$ axis. Both a and b are constants that can be identified by use of the appropriate equations.

Further results reported by Littlewood² indicate that H is small or even negative. Similar results have been obtained in this laboratory. However, a number of authors, such as Keulemans and Kwantes⁸, find no indication of abnormally small λ values.

This investigation was supported by a research grant, A-2402 (C1) from the National Institutes of Health, Public Health Service.

Atomic Weight of Silver

WHILE trying to improve the thermal ionization efficiency of certain elements evaporated from mass spectrometer solid sources, we have had occasion to measure the ratio silver-107 to silver-109, the accepted value of which is 1.055 ± 0.003 due to White and Cameron¹⁻³. Our results do not agree with this value, but rather with the value of 1.0825 given by Hess, Marshall and Urey⁴, and also with an earlier value given by Paul⁵.

For our experiments, we have used four samples of silver, the first was of analytical reagent grade, the second was from bulk silver hallmarked in 1959, the third was of bulk silver hallmarked in 1899, and the fourth was of bulk silver hallmarked in 1791, and we have detected no differences between the ratio silver-107 to silver-109 found in these samples. We have used two mass-spectrometers in this work, the first is a 6-in. radius, 60° magnetic deflexion

machine, and using this machine and the analytical reagent silver the ratio silver 107 to silver 109 was first found to differ from the accepted value¹⁻³. For greater convenience and accuracy the rest of the work was carried out using a Metropolitan Vickers MS 5 30 cm radius, 90° magnet deflection machine. In no case has more than 20 μ m of silver been applied to the ion source filament, and measurements have been conducted on beams of up to 10⁻¹⁰ amp. We have sought for mass discrimination in the ion emission, and have found that this becomes observable only when more than 90 per cent of the sample has been evaporated, and its effect is negligible on the ratio found early in the life of the sample. In Table 1 our results are compared with previous values together with the calculated atomic weight corresponding to each value.

Table 1 RATIO OF SILVER 107 TO SILVER 109 IN NATURAL SILVER

| Author | Ratio silver-107/silver 109 with standard deviation | Chemical atomic weight* |
|--|---|-------------------------|
| Paul (ref. 5) | 1.090 | 107.871 |
| White and Cameron (ref. 1) | 1.055 \pm 0.003† | 107.883 |
| Hess, Marshall and Urey (ref. 2) (4 samples 619 spectra) | 1.0325 \pm 0.0018* | 107.870 |
| Present work | | |
| First machine (2 samples, 53 spectra) | 1.084 \pm 0.002 | 107.893 |
| Second machine (4 samples 420 spectra) | 1.0840 \pm 0.0007†† | |

* Assuming the ratio physical scale/chemical scale = 1.000275 and atomic masses given by Duckworth (ref. 6).

† White and Cameron do not claim better than 1 per cent accuracy (ref. 1).

* Calculated from the results of four samples given in ref. 4 assuming mean deviation 0.03% and standard deviation 0.01%.

†† Calculated from the combined data on four samples of silver.

Hess, Marshall and Urey concluded that their results must have been inaccurate because they did not agree with those of White and Cameron, whose value was concordant with a chemically determined atomic weight of 107.880. This last figure is, however, still subject to dispute, since it involves a nephelometric end point (ref. 7). Our results are consistent with those of Hess et al. within the errors quoted, and we consider it unlikely that the discrepancy between our value and that of White and Cameron could be accounted for by mass discrimination in our instruments.

We conclude that the atomic weight of silver is 107.898 \pm 0.001 (O = 16.0000) based on the mean of the values found in the present work.

A more detailed account of this work will be published elsewhere.

BIOCHEMISTRY

Direct Spectroscopic Examination of Electrophoretic Zones in Agar Gel

ELECTROPHORESIS in agar gel as described by Robinson et al.¹, has been found to be a valuable analytical method in the study of haemoglobin variants. We are now able to extend its scope by carrying out spectroscopic examination of the separate zones directly without extraction from the gel. The value of this technique lies, in particular in the fact that agar electrophoresis can be carried out with minute samples, and also that components present in proportions too small to make their isolation feasible can be examined. At the same time, the difficulty of extracting proteins from the gel is circumvented.

Two methods have been employed for the spectroscopic examination of the zones. In the first of these the logarithmic cam spectrograph² is used; this has the great advantage that non-selective background scattering or absorption does not interfere with the location of fine-structure bands. This method was first used in the study of haemoglobin by Jope³ who found a difference between the positions of the tryptophan fine-structure band of the foetal and normal adult pigments. The method has been used for the analysis^{4, 5} of samples containing haemoglobin F.

The procedure used for the examination of a zone in agar is to cut out and transfer it to a strip of quartz with a small spatula. The agar adheres to the quartz, which is mounted in front of the spectrograph slit. The spectrograms so obtained are indistinguishable from those using a haemoglobin solution. In the case of faint zones the effective path length may be increased by folding the strip on itself.

A number of useful results have been obtained in this way. In the first place we have found that zones attributed to haemoglobin F in ion exchange chromatography^{6, 7} of cord blood haemoglobin have invariably been contaminated with haemoglobin A. It is therefore of interest to establish whether the fractionation of haemoglobin F from other haemoglobins in agar is complete. Examination of the leading zone shows a tryptophan band at 280.6-289.7 m μ , which corresponds to pure haemoglobin F. Similarly, the slower moving zone from cord bloods has its tryptophan band at the wavelength (291.0 m μ) corresponding to pure haemoglobin A. It therefore appears that agar gel electrophoresis does indeed give complete separation of haemoglobins F and A. We have also used the same method to examine adult and foetal monkey haemoglobins and the haemoglobins of other species, as well as some other proteins.

The second spectroscopic method which has been developed is the examination of zones directly in a spectrophotometer. The desired zones are removed as before and mounted on strips of quartz which fit in the cell carriage of the instrument. Measurements are carried out against a control consisting of a piece of clear agar taken from the same layer. For measurements in the visible region the exit beam from the monochromator is allowed to fall on the most intense part of the zone, and for the Soret and ultra violet regions the fainter trailing edge is used. Correct positioning is facilitated by opening the slit of the instrument at a wave length setting in the visible when the incident beam can be seen on the agar strip.

Fig 1 (a) Absorbance (optical density) of 1 mm. layer of 1 per cent agar gel supported on a quartz strip, against a quartz strip as control. The dots indicate the maximum differences in absorbance between pairs of gel samples (see text)

(b) As (a), but with purified agar (see text)

(c) As (a), but dried film

(d) Absorption spectrum, measured in agar gel against an agar control, of a small, very fast-moving brown anodic zone, separated from an old hemoglobin sample. This is presumably identical with a fast-moving anodic component frequently observed in paper electrophoresis of old hemoglobin samples at high pH

The spectrum of a typical sample of agar gel from an electrophoretic layer is shown in Fig 1, curve a. Curve b shows the spectrum of a similar layer prepared from the same agar sample, purified by the procedure described by Bousard and Perrin⁸. Some decrease in background absorption results, but since the matching of agar blanks was not significantly affected, this treatment is unnecessary. Curve c shows the absorption of an agar film which has been allowed to dry down on the quartz strip. It is evident from this that most of the background absorption in the gel above 250 mμ arises from scattering. The absence of specific absorption follows from the known structure of agar.

The matching of two agar strips from the same gel was investigated over the range 250–600 mμ, using 12 pairs of strips from three different batches of agar, as well as a sample purified from one of them as described. The maximum absorbance differences decrease smoothly from ± 0.03 at 250 mμ to ± 0.013 at 600 mμ, the mean differences are about one-half the maximum values.

The loss in accuracy in absorbance readings resulting from background absorption differences between the sample and control strips is not sufficient to vitiate the measurement of adequate spectra (Fig 1), and even absolute measurements, such as those required for the determination of haem-protein ratios⁵, can be made with a fair degree of precision. In a 'Unicam' SP 500 spectrophotometer it was never found necessary to exceed a slit width of 0.4 mm at 250 mμ. Spectroscopy of zones in the dried gel is also possible. If the agar is allowed to dry in the cold, the hemoglobin appears to remain in its native state and good spectra may be obtained, these observations are being further investigated.

The technique described may be capable of extension to other fields. It commends itself in virtue of its simplicity and the very small quantities of material which are required. Many proteins can be characterized, and possibly identified, by the position of their ultra-violet fine-structure bands, which are due to the presence of tryptophan, tyrosine and phenylalanine

residues⁹. The possibility is thus raised of direct characterization of components of such biological fluids, etc., as can be fractionated in agar^{10,11}.

Failure to Recover Infective 'Ribonucleic Acid' from Myxovirus Preparations

It now seems clear that preparations of infective 'ribonucleic acid' can be obtained from crude preparations of many animal viruses, although Colter *et al.* have reported failure with Bunyamwera virus preparations¹. The technique used in most cases is similar to the treatment introduced by Gierer and Schramm², namely, exposure of the virus preparation to concentrated phenol. Recognition that the infectivity of the product of phenol treatment is due to a component other than intact virus is based on such criteria as susceptibility to ribonucleases, stability in different media and rate of sedimentation in the ultracentrifuge^{1,2}.

There is general agreement that the influenza virus particle contains ribonucleic acid but no deoxyribonucleic acid³, and it has been calculated that the amount of ribonucleic acid per influenza virus particle is about the same as is present in particles of polio virus and in those plant viruses which have been adequately studied⁴. It seemed worth while to try to obtain infective 'ribonucleic acid' from influenza virus preparations although it was realized that the influenza virus particle is more complex, both chemically and structurally, than are particles of other viruses such as tobacco mosaic or poliomyelitis. For this purpose, we used a method of phenol treatment which, when applied to crude preparations of Murray Valley encephalitis virus, yielded high titres of infective 'ribonucleic acid'¹. However, the following experiments with influenza virus preparations yielded negative results.

Preparations of different strains of myxovirus, namely MEL, Neuro WS and WSE (influenza A), LEE (influenza B) and Newcastle disease virus (Victorian strain) were obtained in the form of high titre extracts ($E.I.D. 50 = 10^4$ – 10^5) of infected chick embryo lung or infected mouse brain. Phenol treatment of these extracts did not yield a product infective for mouse brain or, by various routes, for the chick embryo.

Phenol treatment of either purified virus⁵ alone ($E.I.D. 50 = 10^{11}$) or of purified virus added to extracts of chick embryo lungs infected with the same strain did not yield an infective product.

In order to see whether any biological activity less than complete infectivity was present in the extracted ribonucleic acid, attempts were made to show recombination on the chorion allantoic membrane of the chick embryo. Several authors* have shown that virus inactivated by heat or by irradiation with ultra violet can recombine with an appropriate active virus. In the present experiments, ribonucleic acid extracted from *WSE*, a strain pathogenic for the chick embryo, was inoculated on to the chorion allantoic membrane with intact *MEL* or *WIS* virus, strains which are non pathogenic for the chick embryo. Recombination was not observed. In other experiments a preparation of ribonucleic acid derived from mouse brain infected with *Neuro WIS* failed to show interference in the mouse brain when the mice were challenged with active *Neuro WIS* virus.

The phenol treatment applied did not extract all ribonucleic acid from purified virus. Both extracted and unextracted ribonucleic acid were found to have similar base ratios.

Production of Serum Albumin and of Globulins by Chick Mesenchymal Tissue and by HeLa Tumour Tissue in Culture

A technique has been described for establishing the autonomous production of well-defined soluble proteins by tissue in culture^{1,2}. The tissue is grown in a medium containing a radioactive amino acid. After incubation, the tissue is homogenized with the medium, the homogenate centrifuged, inactive amino acid added as a hold back carrier, and the proteins in the supernatant separated from all compounds of low molecular weight, including the radioactive amino-acid by ultrafiltration under pressure (autogon). The different proteins are then separated, burnt to carbon dioxide and the radioactivity of the carbon is determined with the very sensitive gas Geiger counter^{3,4}. Radioactivity of the carbon dioxide indicates that the amino-acid has been incorporated into the protein, that is, that proteins have been synthesized from the amino acids by the tissue.

We have now shown that both chick mesenchymal tissue (taken from the legs of embryos 8-10 days old) and human cervix HeLa carcinoma tissue make serum albumin. The mesenchymal tissue was grown after trypsinization of the explants, as a monolayer^{5,6} in roller tubes at 37°C in a medium consisting of chicken fibroblasts was observed by Landsteiner and 4 per cent chick embryo extract, 40 per cent human

ascitic fluid and 56 per cent buffered isotonic salt solution (Goy). The initial number of cells was about 6×10^4 per roller tube. On the third day after the preparation of the monolayer, about $0.5 \mu\text{c}$ ($\sim 10^4$ disintegrations per min) of generally labelled L-tyrosine were added to the medium in each tube and incubation continued for two days. After homogenization, ultrafiltration and thorough washing, the serum proteins were separated by precipitation with alcohol in the cold⁷, and the purity of the resulting fractions checked by electrophoresis of a small part in starch gel and staining⁸. Finally, the bulk of the serum albumin, dissolved in physiological saline, was mixed with antiserum against serum albumin (obtained from rabbits), and the precipitate and the supernatant separately burnt and measured for radioactivity.

After precipitation with rabbit antiserum containing antibody against human serum albumin (anti *HSA*), 94 per cent of the total radioactivity of 0,460 d.p.m. was found in the supernatant fluid in another aliquot after precipitation with rabbit antiserum against chick serum albumin (anti *CSA*). 98 per cent of the radioactivity of 0,110 d.p.m. was found in the precipitate. In the former case the addition of a non radioactive carrier was unnecessary, because of the presence of large amounts of human serum albumin from the nutrient medium, but in the latter case non radioactive chick serum albumin was added to obtain optimal precipitation.

In analogous experiments with the human tumour tissue (here the ascitic fluid in the medium was replaced by human cord serum), the bulk (84 per cent) of the radiocarbon (3,620 d.p.m. in all) went into the precipitate with anti *HSA*, while only 8 per cent of the radiocarbon (3,310 d.p.m.) was found in the precipitate with anti *CSA*. Thus the newly formed serum albumin from the chick tissue and from the human tissue are clearly distinguished. In blank experiments nutrient medium alone without tissue was incubated with the radioactive amino acid: in this case no radioactivity at all was found in the soluble proteins after ultrafiltration and thorough washing.

The α -peptidic linkage of the amino acid in the serum albumin was confirmed by the ninhydrin test⁹. Ninhydrin removes carbon dioxide from those carboxyl groups which adjoin free amino groups. After incubation of mesenchymal tissue with medium containing D,L-leucine labelled at its carboxyl group, isolation of the serum albumin and treatment with ninhydrin, only 4 per cent of the total radiocarbon (2,430 d.p.m.) of the serum albumin was found in the carbon dioxide released, however, if the serum albumin was hydrolysed with hydrochloric acid before treatment with ninhydrin, 85 per cent of the radiocarbon (3,700 d.p.m.) was found in the carbon dioxide.

The *HIM* tissue strain derived from human liver (supplied by Dr I Leslie, Belfast) was also shown, by radioimmunochemistry, to produce serum albumin. Further, radioactive leucine was found to be incorporated in the fractions of α globulin and of $(\beta + \gamma)$ globulin of chick embryo mesenchymal tissue and of HeLa tissue. This was established by determination of the radiocarbon in the proteins separated by precipitation with alcohol and checked for purity by electrophoresis, though no immunochemistry was carried out with these samples.

The production of proteins identical with or closely related to, serum proteins in cultures of

Parker¹⁰, but no detailed assignments were possible with the techniques then available. The extra-hepatic synthesis of serum albumin is of especial interest. In the case of HeLa tissue it is likely that the parent epithelial tissue was capable of making serum albumin, and that this capacity was conserved in cancerization. A full report of our experiments will be published elsewhere. The experiments on the γ -globulins are being continued.

The Behaviour of Haptoglobin during Routine Fractionation

HAPToglobulin is a very interesting plasma protein, because of its specific binding capacity for haemoglobin and the existence of different genetically determined types.

Jayle *et al.*¹ reported the isolation of haptoglobin from the urine of a nephrotic child and from plasma of a haptoglobin-rich individual² by a technique based on precipitation with ammonium sulphate. Laurell³ has recently published a method for preparing haptoglobin from ascitic fluid. Apparently no attempt has been made to prepare haptoglobin during routine fractionation of human plasma. Haptoglobin from ordinary pooled plasma would represent a mixture of the known types of haptoglobin. Mixed haptoglobin would thus be unsuitable for genetic research, but might be used for studies concerning the haemoglobin-binding capacity. But a method allowing the preparation of haptoglobin from pooled plasma would, with slight modifications due to differences in solubility, be suitable for obtaining haptoglobin from a single, well-defined plasma group. However, the additional controls necessary for pooling plasma belonging to a single haptoglobin group would only be acceptable, if a good technique for obtaining haptoglobin was available.

Haptoglobin present in the serum is revealed by paper-electrophoresis after addition of haemoglobin. The complex migrates as an α_2 -globulin. This complex has peroxidase activity. Haptoglobin alone has no such activity, haemoglobin a smaller one than the complex. Haemoglobin migrates as a β -globulin, in the presence of the classical Michaelis-buffer at pH 8.6. Heremans⁴ has proposed a phosphate-buffer of pH 6.8 for the study of haptoglobin-haemoglobin complexes. No migration occurs with haemoglobin alone at pH 6.8, while the complex migrates normally.

This technique permits differentiation between excess haemoglobin and slightly altered haptoglobin-haemoglobin complexes which sometimes have the mobility of a β_1 -globulin. Peroxidase activity is conclusively demonstrated by oxidation of benzidine or anisidine in the presence of hydrogen peroxide.

By both these methods we studied the distribution of haptoglobin in the different fractions resulting from the alcohol fractionation of human plasma (a slightly modified Nitschmann technique⁵).

The only fraction containing haptoglobin in considerable quantities is fraction IV, obtained at pH 5.8 with 33 per cent alcohol. This fraction can be subfractionated by rivanol as recently described⁶. Haptoglobin is still present in the supernatant after the precipitation of ceruloplasmin.

The precipitate obtained from this supernatant by addition of alcohol (35 per cent) at pH 5.9 contains siderophilin (main component), haptoglobin and a small quantity of albumin. The albumin can be removed by rivanol at alkaline pH. Haptoglobin and siderophilin can then be separated by alcohol precipitation at pH 4.4-4.6.

Thus it is possible to prepare haptoglobin together with other plasma proteins during routine fractionation, and pooled plasma obtained from a single haptoglobin group would not be wasted because of the preparation of one minor component of plasma proteins.

Further details will be published elsewhere.

N-Substituted 7-Methoxy-8-Aminomethylchromones and Flavones: New Brain-Stem Stimulants

THE pharmacological screening of various chromone and flavone derivatives has led to the discovery of a new class of brain-stem stimulants, the N-substituted aminomethyl derivatives of these two nuclei, with the following structure

where $R = \text{H}$ or alkyl radical,
 $R' = R'' = \text{H}$ or alkyl radicals,
 R' and R'' can be a part of a cycle,
 $R_2 = \text{H}$ or alkyl or aryl radical,
 $R_3 = \text{H}$ or alkyl radical

The 3 methyl 7 methoxy 8 dimethylaminomethyl flavone (Rec 7 0267) seems to be the most interesting compound, its brain-stem stimulating activity is even higher than that of picrotoxin, the most potent brain stem excitator so far known.

The respiratory stimulating effect of Rec. 7 0267 in normal animals as well as in animals depressed with morphine, is approximately three times higher than that of picrotoxin, 10-20 times higher than that of bemegride and about 200 times higher than that of metrazol.

The brain stem stimulating activity of the compound as measured in animals poisoned by barbiturates, in which the antidotal action of the drug prevents the animals from death is interesting. By administering 2 mgm/kgm of Rec 7 0267 to mice injected with an LD_{50} of nembutal, 90 per cent of the animals survived, in other words 95 per cent of the animals has been saved by the treatment with the new compound.

The minimal active dose ($P = 0.05$) of Rec 7 0267 is 2-3 times lower than that of picrotoxin, 10 times lower than that of bemegride and 27 times lower than that of metrazol.

The safety index (ratio between LD_{50} s and the minimal active dose) was found to be 1.6 times higher than that of bemegride and 2.0 times higher than that of metrazol.

Notwithstanding the brain-stem stimulating activity at therapeutic doses Rec 7 0267 does not show any particular effects on the brain cortex.

The relationships between the pharmacological activity and the chemical structure are significant: the oxygen function (methoxy or hydroxy groups) seems to play a fundamental part in determining the type of respiratory as well as circulatory analeptic activity.

It has been observed that the methoxy compounds act almost exclusively on the respiratory centre while the corresponding hydroxy compounds display a stimulation also on the vasomotor centre causing besides hyperpnea, a prolonged increase of arterial blood pressure.

The optimum position of the aminomethyl chain seems to be 8. It has already been shown¹ that the 6 aminomethylchromones and flavones N-substituted, devoid of the oxygen function in the 7 position display only very slight analeptic activity while acting as papaverine like antispasmodics.

In the specific case of the flavone derivatives simultaneous displacement of the basic chain and of methoxy group from 8 to 4,3 positions causes a considerable loss of activity. The presence of alkyl groups at the nitrogen seems also to be fundamental since the unsubstituted ones are inactive.

The activity increases in marked degree in the monosubstituted derivatives, the N-methylamino methyl compounds, and reaches a maximum for the compounds with two substituents at the nitrogen (also when the substituents are a part of a cycle).

Stimulatory Effect of Foreign Compounds on Ascorbic Acid Biosynthesis and on Drug-Metabolizing Enzymes

PREVIOUS studies in rats have shown that drugs such as Chloretone¹, barbital, phenobarbital and amino pyrine can stimulate the biosynthesis of L-ascorbic acid from glucose through the glucuronic acid pathway²⁻³ as follows

Evidence for this has come from the observations that these drugs markedly increase the urinary excretion of L-ascorbic acid and that they stimulate the conversion of glucose-1-¹⁴C to labelled D glucuronic acid, L-gulonic acid and L-ascorbic acid²⁻³. In the present study the following compounds were also found to be potent in stimulating the biosynthesis of L-ascorbic acid: the antirheumatic drug phenylbutazone, the muscular relaxant orphenadrine (2-dimethylaminoethyl 2-methyl benzhydryl ether), and the carcinogenic hydrocarbons 3-methylcholanthrene, 1,2,5,6-diben-zanthrone and 3,4-benzpyrene. Phenylbutazone and orphenadrine in doses of 20-50 mgm/day for 4 days to adult rats produced about a 20 fold increase in L-ascorbic acid excretion. The striking effect of a single 10 mgm dose of 3-methylcholanthrene on the urinary excretion of the vitamin is shown in Fig. 1. By 6 days

Fig. 1 Stimulation of L-ascorbic acid excretion by 3-methylcholanthrene. A male Wistar rat (250 gm) was injected intraperitoneally with a single 10 mgm dose of 3-methylcholanthrene in 0.5 ml corn oil and the daily urinary excretion of L-ascorbic acid was measured by titration with 2,6-dichlorophenolindophenol dye. A milk diet free of vitamin C was used in this study (ref. 2). Similar doses of 1,2,5,6-diben-zanthrone or 3,4-benzpyrene to rats (250-300 gm.) resulted in a 20- to 100-fold increase in L-ascorbic acid excretion by 5 days.

after administration the urinary excretion was 50-75 times greater than the control value and in fact during the 19-day period about 140 mgm of L-ascorbic acid was excreted. This represents a minimum value for the total L-ascorbic acid synthesized since the vitamin is extensively metabolized in the rat⁴.

The observation that the carcinogenic hydrocarbons are potent stimulators of L-ascorbic acid biosynthesis is of particular interest since these compounds are also known to be extremely potent in inducing the synthesis of several liver microsomal enzymes which metabolize foreign compounds^{5,6}. These biocatalysts are closely related to a variety of drug-metabolizing enzymes in liver microsomes⁷. The marked effect of other compounds which stimulate L-ascorbic acid biosynthesis to increase the activity of one of these

¹ Da Re, P., Verlicchi, L., and Setnikar, I. (in the press)

microsomal enzymes, azo dye demethylase, is shown in Table 1. The striking effectiveness of phenobarbital

Table 1 INCREASED ACTIVITY OF AZO DYE DEMETHYLASE CAUSED BY THE ADMINISTRATION OF VARIOUS FOREIGN COMPOUNDS

| Compound | Dose mgm./day | Demethylase activity |
|-----------------------|------------------|----------------------|
| Control | — | 5 |
| Chloretone | 4.3 | 15 |
| Barbital | 5.0 | 21 |
| Phenobarbital | 1.0 | 25 |
| Thiopental | 2.0 | 17 |
| Aminopyrine | 11.2 | 13 |
| Phenylbutazone | 7.5 | 14 |
| Orphenadrine | 3.8 | 12 |
| 3-Methylcholanthrene* | 0.1 | 15 |

Male Holtzman rats (40–50 gm.) were maintained on a synthetic diet (ref. 7) and were injected twice daily for 4 days. The animals were killed on the fifth day and the demethylation of 3-methyl-4-monomethylaminoazobenzene was determined in fortified whole liver homogenate as previously described (ref. 7). The demethylase activity represents the $\mu\text{gm.}$ of 3-methyl-4-aminoazobenzene formed per 50 mgm. liver per 12 minute incubation. Each enzyme activity represents pooled livers from at least 4 animals. The variation in enzyme activity of controls was less than $\pm 1 \mu\text{gm.}$ in 10 experiments.

* These animals were killed 24 hours after a single injection.

to stimulate the activity of this demethylase is demonstrated in Fig. 2. Further experiments were

Fig. 2 Effect of phenobarbital on the activity of azo dye demethylase. Male Holtzman rats (40–50 gm.) were fed a synthetic diet (ref. 7) and were injected intraperitoneally with 5 mgm. of phenobarbital. The animals were killed at intervals after drug administration and the demethylation of 3-methyl-4-monomethylaminoazobenzene by fortified whole liver homogenate was determined (ref. 7). The demethylase activity represents $\mu\text{gm.}$ of 3-methyl-4-aminoazobenzene formed per 50 mgm. liver per 12 minutes incubation. Each point represents the values obtained on 4 animals.

carried out to test the activity of barbiturates on other liver microsomal enzymes. The intraperitoneal administration of phenobarbital (3 mgm./day for 4 days) or barbital (7 mgm./day for 6 days) causes appreciable increases in the activities of the enzymes which reduce the azo linkage of aminoazo dyes and which hydroxylate 3,4-benzpyrene and zoxazolamine.

It is likely that phenobarbital and the other active drugs, like the polycyclic hydrocarbons, induce the synthesis of azo dye demethylase. The addition of phenobarbital *in vitro* to liver homogenates did not affect the activity of this enzyme. No evidence was found that activators or inhibitors caused the increased enzyme activity. Furthermore, pretreatment of the rat with ethionine, which has been used to inhibit induced enzyme synthesis, was found to block completely the effect of phenobarbital on demethylase activity and methionine prevents this inhibitory action of ethionine.

The results presented here show that foreign compounds differing widely in chemical structure and pharmacological activity have the dual property of stimulating the biosynthesis of L-ascorbic acid and of increasing the activity of certain drug-metabolizing enzymes in liver microsomes. The finding that the same compounds exert both actions suggests a possible relationship between these two responses. It is of particular interest that one of the most potent compound in each case is barbital, a drug which is not metabolized or conjugated but is excreted unchanged in the urine³. These effects may represent adaptive responses on the part of the body to foreign compounds by a mechanism which does not involve the adrenal gland^{3,7}. Further studies are now under way to elucidate the nature of these biochemical responses.

Spectrophotofluorometric Assay of Griseofulvin

ALTHOUGH griseofulvin was isolated twenty years ago¹ its value as a systemic anti-fungal agent was not appreciated until 1958, when Gentles² reported that he had eradicated experimental ring-worm in guinea pigs by its use in oral treatment. Clinical reports^{3–5} that have appeared since have evoked considerable interest among dermatologists and seem to have justified Gentles' optimism.

We are currently studying the absorption, distribution and excretion of griseofulvin in laboratory animals and man, to facilitate these studies we have developed a simple and rapid spectrofluorometric assay. We give here the details of the assay and indicate briefly our findings to date.

A 1 per cent ethanolic solution containing 0.5 $\mu\text{gm.}$ griseofulvin/ml was scanned on a Farrand spectro photofluorometer. The spectra obtained are shown in Fig. 1. The activating spectrum contains two well defined peaks, one at 295 m μ and another at 335 m μ (uncorrected values). For assay purposes, an activating wave-length of 295 m μ and an analysing wave-length of 450 m μ were chosen. Choice of slit-widths depends on the characteristics of the photomultiplier tube. A 1 per cent ethanolic solution containing 0.05 $\mu\text{gm.}$ griseofulvin/ml fluoresces twice as strongly as 1 per cent ethanol, a full-scale deflection is obtained on the most sensitive range at a concentration of 0.5 $\mu\text{gm.}/\text{ml}$. The intensity of fluorescence increases linearly over the concentration range 0.05–0.5 $\mu\text{gm.}/\text{ml}$ and is independent of pH over the range 3–10. Below pH 3 the fluorescence decreases sharply. Temperature of the solution is important,

Fig. 1 Fluorescence spectra of griseofulvin

Because the fluorescence decreases with increasing temperature. Over the range 10–25° C the change is linear, and each degree rise results in 2.5 per cent less activity than at the lower temperature.

Before attempting any assay of griseofulvin by the method described, all glassware (syringes, flasks, shake tubes, pipettes, cuvettes, etc.) must be cleaned in chromic acid and rinsed with distilled water and 1 per cent ethanol. Detergents should be avoided. The final 1 per cent ethanol washings are checked on the spectrofluorometer before the apparatus can be considered suitable for use.

A small sample (1 ml or less) of blood, plasma, serum or urine is mixed with 1 ml of 1 per cent ethanol and shaken for 15 sec with 10 ml of other light ml of the other phase (total volume after shaking = 9.7 ml) are removed and evaporated to dryness. The residue is dissolved in 10 ml of 1 per cent ethanol, and the fluorescence of the solution is measured against a griseofulvin standard (0.5 μgm/ml) at the same temperature. Pre-dosage samples of blood, plasma, serum or urine, with and without added griseofulvin, are included in each set of assays. Blood, plasma and serum have similar blank values, which do not vary greatly between either individuals or species (rat, guinea pig, rabbit and man). Griseofulvin added to heparinized blood at concentrations ranging from 1 to 5 μgm/ml gave percentage recoveries averaging 90 ± S.E. 1.4 (25 assays). At 10 μgm/ml the average recovery fell to 84 per cent ± 1.1 (10 assays). Blank urine values differ greatly both between individuals and between samples taken from the same individual at different times. However, it is possible to overcome most difficulties by raising the pH of the urine to approximately 10 before extracting with ether. The mean percentage recovery of griseofulvin added to human urine over the concentration range 1–5 μgm/ml was 90 ± 2.9 (30 assays).

An experiment was conducted to test the agreement between microbiological and spectrofluorometric assay results. Three volunteers were given single oral doses of griseofulvin (0.5 gm), and serum levels were determined at intervals over the next twenty-four hours. The samples were assayed both microbiologically by Dr P. W. Mingleton and his colleagues using a *Microsporum canis* tube assay that they have developed in these laboratories and by the spectrofluorometric method. The results are compared in Fig. 2. The half-life during the decay period is approximately eight hours.

Fig. 2 Serum-levels of griseofulvin in man after single oral dose of 0.5 gm. —●— biological assay; —○— spectrofluorometric assay. Each value represents the group mean for three individuals.

To determine the effect of dosage on serum levels three groups of three volunteers were given single oral doses of 0.25, 1 or 2 gm. The serum levels which were determined spectrofluorometrically at 2, 5 and 9 hr are shown in Fig. 3. During the first

Fig. 3 Serum-levels in man after graded oral doses of griseofulvin. —○— 2 gm. per man; —●— 1 gm. per man; —○— 0.25 gm. per man. Each value is the group mean for three individuals.

8 hr after administration the average amount of griseofulvin found in the urine of the group dosed with 1 gm was 0.5 mgm and the corresponding value for those given 2 gm was 0.6 mgm.

The work described above continues and it is hoped to present further results for publication.

Calcium Ions and the Permeability of Human Red Cells

It is well known that many tissues when placed in an electrolyte medium are profoundly affected by the presence or absence of calcium ions. This is also true of the red cells of the tortoise¹, of the snapping turtle² and probably of the red cells of certain fishes³⁻⁵, which in a calcium-free electrolyte medium become highly permeable to cations, and hence swell and rupture (haemolysis). The red cells of the frog, chicken and of *Mammalia*, however, are little affected by suspension in calcium-free sodium chloride solution, exchange of cations with the external medium being very slow, and haemolysis correspondingly delayed. Nevertheless dependence on calcium of the human red cell may be demonstrated after suitable treatment of the cells in conformity with earlier work by Maizels⁶ and Wilbrandt⁷. The former showed that human red cells became highly permeable to cations when placed in an electrolyte-free medium (for example, glucose), unless about 10 mM sodium or potassium chloride were present, while Wilbrandt found sodium and potassium chlorides to be less effective than the salts of the alkaline earths, though there was no specificity within this group, the actions of calcium, magnesium, strontium and barium being quantitatively similar.

The treatment of red cells used in the present investigation involves three stages, details of which are shown in Table 1. In stage 1 (depletion stage) red

Table 1 EFFECTS OF THE SALTS OF THE ALKALINE EARTHS ON THE PERMEABILITY OF MODIFIED HUMAN RED CELLS TO MONOVALENT CATIONS

| Additions | mM | Ratio of the cation flux per hour to the concentration difference between cells and the external medium | | |
|-------------------|-----|---|---------------|-------------|
| | | Sodium in | Potassium out | Lithium out |
| None | — | 0.31 | 0.28 | 0.44 |
| MgCl ₂ | 2.5 | 0.28 | 0.31 | 0.41 |
| SrCl ₂ | 2.5 | 0.25 | 0.25 | 0.35 |
| BaCl ₂ | 2.5 | 0.30 | 0.31 | 0.43 |
| CaCl ₂ | 2.5 | 0.04 | 0.06 | 0.07 |

Note. Cells were first incubated for 3 hr. at 37° C in lactose solution (6 per cent w/v), then for 1½ hr. in a solution of potassium and lithium chloride (70 mM of each), and finally transferred to sodium chloride solution (140 mM) for 1 hr. at 37° C. Additions of calcium chloride, magnesium chloride, etc. were made at the beginning of the last stage, during which cation exchanges were measured.

cells are incubated in lactose solution, which increases permeability twenty-fold. Natural sodium and potassium leak from the cells accompanied by water and the cells shrink. In stage 2 (cation replacement stage) the cells are transferred to an electrolyte medium, one containing a mixture of potassium and lithium chloride is suitable. Here, potassium chloride, lithium chloride and water enter the cells, and it would be possible to measure penetration-rates in this stage, were it not for the uncertainty in correcting for the considerable swelling which now occurs. Hence it is necessary to proceed to stage 3 (cation exchange stage) and transfer the cells (now containing potassium and lithium) to a different electrolyte medium, usually sodium chloride solution. In this stage potassium and lithium leave the cells, whilst sodium enters, changes in volume of the cells being slight. If to a series of such suspensions, chlorides of magnesium, strontium, barium or calcium are respectively added, cation penetration is rapid in the case of the first three, and slow in the presence of calcium. This is shown in Table 1 where permeability is expressed as the ratio of the cation flux per hour to the mean difference in concentration between cells and medium.

Maizels' and Wilbrandt's earlier observations suggest that if red cells are suspended in a solution of non-electrolyte and monovalent cations or certain divalent cations are added at once, then normal low cell permeability is maintained, and that in the absence of such cations low permeability is lost. The present observations show that once relative impermeability has been lost in this way, calcium alone can restore it. This may well be true of other cells, including the unfertilised egg of the sea-urchin which in sea-water is only slightly permeable to water, but becomes highly permeable in non-electrolyte media unless either calcium or magnesium chloride is added⁸. It is suggested that some substance is present in the red cell membrane which contributes to low permeability, that loss of this substance is prevented by various cations, but that replacement can only be effected by calcium. It is possible that the substance itself is a calcium compound, if so, it can only be present in trace amounts.

Splenic Siderosis in Mice Treated with Dithiourethane

In an attempt to elucidate the mode of action of urethane (ethyl carbamate) as a carcinogen for mice, its dithio analogue (NH₂CSSC₂H₅) was prepared^{1,2} and a study was made of its lethal dose and general toxic effects before testing it for carcinogenicity. A report of the latter is in preparation. The short-term tests revealed an action of this compound whose significance is, at the moment, rather obscure.

CBA strain mice of both sexes were injected subcutaneously with 0.15 ml. of a 5 per cent solution of dithiourethane in arachis oil. After three or more weekly injections, a brown pigment in haematoxylin and eosin-stained sections of the spleen was seen in all cases. When, on a few occasions, stock outbred mice were used, the same phenomenon occurred. The pigment also appeared in unstained sections and was found to contain iron by the Prussian blue test. It was distributed in the macrophages of the perfollicular reticulo-endothelial tissue (Fig. 1). The spleens of mice injected with the solvent (arachis oil) alone, of mice treated with 0.2 ml. of a 5 per cent aqueous urethane solution for the same time and of untreated mice, all showed considerably smaller amounts of the pigment scattered throughout the spleen (Fig. 2). A number of other organs of the same mice were examined histologically as a routine in these tests, and no evidence of this pigment was ever found in liver, kidney, lung, axillary lymph node or testis. Nor was any seen in pancreas when, on occasion, a piece was accidentally included in the section with spleen.

In the long-term experiments, weekly injections were carried out for up to three months. The amount of pigment deposited in the spleen was found to be proportional to the number of treatments during that time. When treatment stopped the amount of pigment

Fig. 1. Spleen of dithiourethane-treated mouse stained for iron (Prussian blue method $\times 55$)

Fig. 2. Spleen of control mouse injected with the solvent (arachis oil) similarly stained ($\times 55$)

decreased slowly over the following three months when detectable amounts were still present. As the amount of siderosis increased with treatment the spleens became noticeably darker in colour when compared to those of untreated mice. While the spleens were not weighed there was never any apparent change in the size of those from treated mice. The mice themselves always appeared perfectly well and healthy and showed no loss of body weight, even when the above mentioned dose was given twice weekly for one month.

A number of possible explanations for this phenomenon were considered. A haemolytic effect of the dithiourethane might have been responsible but neither decreased erythrocyte counts nor increased erythrocyte osmotic fragility was found in the treated mice.

Since the haemoglobin content of the mice was normal and the splenic iron was so markedly increased, the next investigation was to determine the total iron content of the dithiourethane treated mice compared with controls. The iron assay was done by titration of the ferrous to ferric iron with dichromate by the standard method. In order to obtain sufficient iron for a 2 ml titration (error of titration not more than 2 per cent) about 8 mice had to be pooled. In the first instance, 8 *CBA* mice were given eight biweekly injections of dithiourethane (same dose as above). 8 were given injections of the arachis oil solvent and 8 were untreated. Each group of mice was then sacrificed, weighed and incinerated carefully in fused quartz crucibles at 500°–600° C. The ashes were extracted with about 5N hydrochloric acid and the extracts from each group pooled. The results for the experimental mice solvent injected controls and untreated controls were respectively 74, 63 and 61 mgm. of iron per kgm. body weight.

This was repeated on two groups of treated mice (9 and 8 *CBA*) and two groups of solvent treated controls (9 *CBA* mice in each). The figures in this case were 72 and 68 mgm. iron/kgm. for the experimental mice and 53 and 51 mgm. iron/kgm. for the controls. These results suggest that the total iron content of the dithiourethane-treated mice was increased. Consideration was given to the possibility that the normal mechanism of iron absorption through the gastro-

intestinal mucosa was interfered with allowing larger amounts than normal to be absorbed, the excess being taken up by the splenic macrophages. On the other hand dithiourethane may have had a specific effect on the spleen resulting in an increased rate of erythrocyte destruction. The relatively large amounts of pigment deposited would indicate the temporary removal of iron as a readily utilisable source from the animal's store, with resultant increased absorption from the gut as compensation. The erythrocyte destruction being relatively slow the compensation would occur fast enough to prevent any marked anaemia, and the mouse's total iron content would thus increase. This appears to be the most likely explanation of an increased total iron content of the mice showing siderosis only of the spleen.

This work was carried out at the Cancer Research Department of the London Hospital Medical College. Expenses were partly defrayed out of a block grant from the British Empire Cancer Campaign.

The Infra-red Gas Analyser as a Means of Measuring the Carbon Dioxide Output of Individual Insects

It has been known for some time that some insects (larvae, pupae and adults) may discharge the carbon dioxide produced during metabolism either as a continuous stream or in bursts¹⁻⁴. Pant using a diaphragmometer, was able to demonstrate changes in the concentration of carbon dioxide but he points out that the sensitivity of his instrument was always adapted to the amount of carbon dioxide produced and was calibrated for this amount. Thus his graphs from different animals cannot be compared with one another, whereas those made using an infra red analyser can be compared.

Using the infra red analyser it is possible to observe and record whether the carbon dioxide is produced in bursts (Fig. 1) or as a continuous stream (Figs. 2, 3 and 4). Also, by using a planimeter on the recording it is possible to calculate the mean output of carbon dioxide per insect per minute. The analyser used by me was specially built by the Infra Red Development Company to suit my requirements. It has three ranges (per cent) 0.0 to 0.02, 0.0 to 0.2 and 0.15 to 1.0 for the complete deflexion of the galvanometer and of the grapho recorder (response time 0.6 sec.) it is possible to switch from one range to another simply by

Figs 1-4 Recordings showing the carbon dioxide output of adult locusts. Fig 1, newly merged. Figs 2 and 3, 5 days after emergence. Fig 4, 70 days after emergence.

a tap and/or altering a switch. All the recordings given here were made on the 0.0 to 0.2 per cent range with the graphic recorder running at 6 in./hr. The rate of flow of air over the insect was so controlled that it was equivalent to 100 ml/min at 0°C. Thus it is possible to give the results as microlitres per insect per minute at 0°C.

All experiments were carried out with the insect (male, *Schistocerca gregaria* Forsk.) in a tube, in the dark, in a constant temperature bath at 32°C, and at a relative humidity between 60 and 70 per cent. Carbon dioxide free air was pumped into the tube and the air leaving the tube passed through the analyser, the cooler and finally through the flow-meter. Each experiment lasted 2-3 hr. The recordings given here are for the second hour of the experiment because, in the majority of the experiments, it was found that the metabolic rate was higher and more erratic during the first 20-40 min. than after this initial period. It is thought that this high metabolic rate at the beginning of the experiment is due to the locust being handled. If, as in all these experiments, the locust is kept in the dark then it settles down more quickly and the output of carbon dioxide remains more constant than if it is in bright light. It should be noted at this stage that by 'constant' is meant for a period of 2-3 hr, but if the recording is continued for 24-48 hr, without the locust feeding, then a drop in output of carbon dioxide does occur. At first the analyser was kept at laboratory temperature and its temperature was controlled by a heater and thermostat. This was soon found to be insufficient control for an analyser as sensitive as mine, so the thermostat and heater of the analyser were removed and the whole apparatus placed in a constant-temperature cabinet at 26°C. The actual temperature of the cabinet is of little importance provided it remains constant once the analyser has been zeroed and standardized against a gas of known concentration.

As a full account of this work will be published elsewhere, I propose to give here only a few typical

recordings of the output of carbon dioxide of male *Schistocerca gregaria* adults to show the advantages of this method of measuring the carbon dioxide output. Fig 1 is a recording of an adult 3 hr after shedding the last hopper skin. At this age, carbon dioxide is produced in bursts at the rate of 24 bursts an hour, but there is considerable individual variation in the number of bursts an hour. After the locust was removed from the analysing apparatus it was placed in a tube under the binocular microscope in order to investigate the opening and closing of the spiracles. It was still in the dark except for small peep holes through which the spiracles could be observed. Also a stream of air was passed through the tube so conditions were very similar to those in the analysing apparatus. It was observed that the bursts of carbon dioxide were produced by the locust stopping all respiratory movement and closing all spiracles for 1½ min (average). At the end of this period respiratory movements would start and the spiracles would start to open and close at the rate of one opening per second (average) for 15-30 sec. This was generally followed by a short period (5-1 sec) when the spiracles opened once every 5 sec. Then the spiracles would remain closed and the cycle would be repeated. These times are by no means constant, indeed, it can be seen from this recording that all bursts are not identical. It should be noted that there is a small amount of carbon dioxide produced between the bursts. As all respiratory movements ceased, and all spiracles appeared closed during this period, the small amount of carbon dioxide produced must be the result of a slight leakage through the closed spiracles or diffusion through the general surface of the locust. At this age the cuticle of the locust is still fairly soft, so that it is just possible for diffusion to take place. As adult locusts seldom start feeding until at least 12 hr after moulting, they must, at this age, be utilizing the reserve food (fat) stored in the body and the burst method of breathing is obviously the best for the conservation of water. The mean output of carbon dioxide for Fig 1 is 20.12 μl/locust/min, which agrees fairly well with the results obtained chemically⁶ and it is well within the range observed in these experiments. By the time the locust has been in the adult stage for one day and has started to feed, the bursts of carbon dioxide have been replaced by a continuous stream of the gas, which varies in amount from time to time.

Fig 2 is a recording of an adult 5 days after shedding the last hopper skin. The carbon dioxide is no longer produced in bursts but as a continuous stream. The small changes in the amount of carbon dioxide are the result of changes in the rate of the respiratory movements and in the rate of opening of the spiracles. At this age the rate of opening of the spiracles varies from 25 to 55 per min but they never remain closed for more than 3 sec at a time. The peaks on this recording (a single at 35 min and a double one between 53 and 55 min) are, I think, the result of a sudden change in the respiratory rate due to some very slight movement of an antenna or a leg. If the locust does try to move along the tube, then a rapid increase in the respiratory rate occurs and is continued for some minutes, as for example, between 14 and 24 min on the recording in Fig 3. At this age locusts are heavy feeders and are utilizing fresh food, so the necessity for conserving water by discharging the carbon dioxide in bursts does not arise. Also they tend to be more active. The mean output of carbon dioxide for Fig 2 is 40.77 μl/locust/min and for Fig 3 it is 44.72 μl/locust/min.

Fig 4 is a recording of an adult 70 days after hatching the last hopper skin. This is old for a locust kept at 32° C and a relative humidity of approximately 55 per cent. At this age the results are very variable but this recording is of the average type. It shows that the main output is around the 20 μ l mark with very distinct and fairly regular bursts superimposed upon it. The mean for the whole recording is 27.80 μ l/pocust/min.

Recordings made less than 24 hr prior to death (from natural causes) of the locust show the burst type of respiration similar to that for newly emerged adults except that the intervals between the bursts, when the spiracles are closed, are much longer.

Although the recordings given here were made over short periods, it is possible, with this analyser, to make continuous recordings extending over 24, 48 hr or longer.

I am indebted to the Central Research Fund of the University of London for a grant which made this work possible.

Anticoagulant Activity of Human Arterial Mucopolysaccharides

THE isolation of acid mucopolysaccharide material from human aortic tissue was reported in a previous publication¹ from this laboratory. Analysis of the isolated material² and of components separated by paper electrophoresis³ indicated that the major part of the material consisted of chondroitin sulphate. The presence in the material of a fraction susceptible to the action of staphylococcal hyaluronidase⁴ and of a sulphated component containing both galactosamine and glucosamine⁵ was also observed. The isolation of heparin sulphate from human aortic tissue has recently been reported by Linker, Hoffman and Meyer.⁶

Of the sulphated mucopolysaccharides present in various connective tissues three possess anticoagulant activity, namely α heparin chondroitin sulphate B (β heparin), and heparin sulphate. Although α heparin has been isolated from the aorta of cattle⁷, this sulphated mucopolysaccharide has not been identified in the acid mucopolysaccharide material extracted from the intima media layers of human aortic tissue. The present study was undertaken with the purpose of determining the anticoagulant activity of acid aortic mucopolysaccharide samples from subjects of various ages.

Extraction of mucopolysaccharide material was made from the intima media layers of 27 samples of the descending thoracic aorta by the procedure of Dyrby and Kirk.¹ Since the average yield of sulphated mucopolysaccharides obtained by this procedure is about 60 per cent of the acid hydrolyzable sulphate present in the arterial tissue the samples may be considered as being fairly representative of the tissue content of these compounds. The age of the subjects from whom the samples were obtained ranged from 3

to 76 years. The average percentage composition of the samples was sulphate (SO₄), 12.5, hexosamine, 24.2, uronic acid, 33.5, 80 per cent of the hexosamine was galactosamine and 20 per cent glucosamine. No significant change with age was found in the sulphate content of the samples.

The anticoagulant activity of the mucopolysaccharide material was determined by the procedure of Freeman, Engolberg, and Dudley.⁷ Each of the 27 samples was tested at four different levels by addition of 100, 200, 400, and 800 μ g of the material, dissolved in 0.9 per cent sodium chloride solution, to aliquots of the plasma. After 5 min incubation the calcium chloride reagent was added and the coagulation time recorded. A high reproducibility of the results was observed when determinations were performed with the same samples on different days. A coagulation time test with heparin sodium (US Pharm) added in quantities of 0.4, 0.8, 1.2, 1.6, 2.0 and 2.4 μ g was run with each set of experiments. For comparative purposes the anticoagulant activity of a commercial chondroitin sulphate A preparation from the cartilage of cattle was likewise determined.

The results of the investigation are presented in Fig. 1. It will be seen from the reported values that the arterial mucopolysaccharide material was found to possess a definite, but low anticoagulant activity. When compared on a weight by weight basis, the anticoagulant activity of the material was less than 1 per cent of that exhibited by heparin sodium (α heparin), but was considerably greater than the activity observed for the commercial chondroitin sulphate A preparation. The anticoagulant activity of mucopolysaccharide samples from children was moderately higher than that recorded for samples from adults, but the number of samples obtainable from children was too small to permit definite conclusions with regard to this point.

The observed anticoagulant activity of human arterial mucopolysaccharides may constitute a factor

Fig. 1. Comparison of anticoagulant activities of human arterial acid mucopolysaccharide material, heparin sodium (US Pharm) and chondroitin sulphate A.

of significance in connexion with Duguid's⁸ theory concerning the etiology of atherosclerosis

The investigation was supported by grants from the National Institutes of Health, Public Health Service (PHS-891) and the Life Insurance Medical Research Fund (G-56-54)

Urethane as a Carcinogen and as an Anaesthetic for Fishes

PROBABLY the most important factor which determines the carcinogenic properties of a substance is the species (and sometimes the strain) of the animals which are being treated with it. This makes it very difficult to deal with such substances from the public health point of view since results from animal experiments in the field of cancer research cannot always be related to what may happen in man. In practice, substances with known marked carcinogenic activity for man or animals, and which are liable to constitute an occupational hazard, are usually recognized and treated with the respect due to them.

There is one possible exception which we feel warrants more publicity than it has received in the past. Urethane (ethyl carbamate) was found to induce tumours of the lung in mice¹ and rats², and since then has been found carcinogenic for other mouse tissues to a lesser extent³. This compound was not found to be carcinogenic for other species so far tried (rabbits⁴, chickens and guinea-pigs⁵), but nevertheless, the possibility of such an action in man cannot be ignored. Furthermore, evidence was presented that urethane was absorbed in carcinogenic doses from mouse skin^{6,7} and warning was given⁶ to those who handle the compound not only of its possible carcinogenicity, but of its known leucopenic effects on man⁸. Since then, absorption from human skin has also been noted⁹.

A common way of anaesthetising fishes and aquatic invertebrates is to immerse the animals in an aqueous solution of urethane. Wood¹⁰, in a journal of comparatively limited circulation, stressed the risks to the operator in this process, but it appears that even now an appreciable number of people who deal with this substance are unaware of its possible effects. We would suggest, first, that when its use cannot be avoided, reasonable precautions should always be taken to prevent contact of urethane with the skin and secondly that its use as a fish anaesthetic should be discontinued. As a substitute, we recommend tricaine methane sulphonate (*M.S. 222* Sandoz), in the light of the fact that no deleterious effects, as with urethane, have been reported following its use so far.

M.S. 222 has given excellent results in anaesthesia with a wide range of fishes and amphibians^{11,12}. The optimal solution strength to be employed is known to vary with species, individual size and temperature^{11,12}, and suitable concentrations must be determined

empirically for every species and in different situations. A 1 in 2,000 solution has been used successfully in operations on goldfish^{13,14}, brown trout, *Mollenes latipinna* and axolotls¹⁴. Pickford¹⁵ used a 1 in 3,500 solution for *Fundulus heteroclitus*, and a 1 in 5,000 solution is suitable for eels (*Anguilla anguilla*). Various concentrations have been employed by many different workers on amphibian embryos, larvae and adults, and at least one worker has used *M.S. 222* to anaesthetise planarians¹². Apart from its use in the laboratory, this substance is excellent as an anaesthetic to immobilize hatchery and wild fishes during tag and fin-clipping and measuring operations, or to 'traquillize' various game, pet and ornamental fish during transport¹², and Gilbert and Wood¹⁷ report that the palatability of sharks and rays anaesthetized with *M.S. 222* was not affected, and that no deleterious effect was observed in people who ate these fishes.

Composition of the Hæmolymph of *Petrobius maritimus* Leach

A CONSIDERABLE amount of information concerning the hæmolymph composition of pterygote insects is available, but nothing has been known about hæmolymph composition of any apterygote insect.

Specimens of *Petrobius maritimus* Leach (Aptergota, Thysanura) were collected from under stones just above high-tide line of the Firth of Forth. The dorsal thoracic intersegmental membrane was punctured to obtain hæmolymph. In most cases, hæmolymph from several individuals was pooled. Osmotic pressure, sodium, potassium and chloride concentrations were determined as previously described¹. So far as possible a determination was carried out in duplicate or triplicate on any one sample; many cases the osmotic pressure and several values were determined on the same sample.

The mean values and standard errors are given in Table 1. The numbers in brackets are the number of different samples on which determinations were carried out.

Table 1

| | |
|-------------------------|---------------|
| Osmotic pressure, mM/l. | 232 ± 3 (9) |
| Sodium, mE/l. | 208 ± 4 (7) |
| Potassium, mE/l. | 5.8 ± 0.3 (8) |
| Chloride, mE/l. | 194 ± 5 (9) |

The osmotic pressure of *Petrobius* haemolymph, although high, is very much less than that of sea water end of *Ligia*¹ which lives in the same habitat. This suggests that *Petrobius* is not a relic of a group that might have colonized the shore from a true marine environment.

In *Petrobius* the bulk of the haemolymph osmotic pressure is accounted for by sodium chloride. This is similar to the aquatic Crustacea, the isopod *Ligia*², the spider *Tegenaria*³ and Diplopoda⁴, but is different from the Pterygota. In the Pterygota the chloride concentration is usually low compared to the total cation concentration, and it appears probable that a high concentration of organic anions is present. Also the cations considered to be present as ionized salts account for only a fairly small proportion of the osmotic pressure. These characteristic features of the haemolymph of pterygote insects presumably could be regarded as specializations that have appeared subsequent to the apterygote level of organization. But *Petrobius* is eating seaweed detritus that would be expected to have a high concentration of potassium chloride⁵, and a high concentration of this chloride in the diet markedly decreases the chloride organic anion ratio in the haemolymph of *Drosophila* larvae⁶. It would thus be of interest to compare the haemolymph of some non littoral apterygote insect with *P. maritimus*.

In Pterygota the haemolymph sodium:potassium ratio appears to be associated with the diet, and in phytophagous insects is low, but in *Petrobius* the sodium:potassium ratio is very high. Although seaweed detritus probably has a high potassium concentration, the sodium concentration is also likely to be high, and, if we regard a low sodium:potassium ratio as an adaptation primarily to low sodium availability, the *Petrobius* ratio is as would be expected.

Disappearance of the Erythropoietic Factor from Plasma of Anemic Dogs after Nephrectomy

In previous communications it was shown that bilateral nephrectomy abolished erythropoiesis in the dog^{1,2} whereas ureter ligation did not impair erythropoiesis despite a similar state of intoxication and malnutrition³. From these observations as well as the demonstration by Jacobson *et al.*⁴ that an elevated erythropoietin level was not obtained in hypoxic rats after nephrectomy, it was suggested that the kidney may be the site of production of one erythropoietic stimulating substance.

In a recent paper erythropoietin response was demonstrated in plasma and urine of the dog when severe anemia was produced⁵. The present study discloses the failure of erythropoietin production by dogs similarly anemic after bilateral nephrectomy. Additionally, the rapid disappearance of the erythropoietic factor after ablation of the kidneys was demonstrated.

Fig. 1. Erythropoietic activity of plasma from bled dogs with regard to corresponding hematocrit.

Twelve mongrel dogs weighing between 12 and 20 kgm were used. Six dogs were bled once or twice daily to hematocrit values from 5 to 11 per cent. Blood volume was maintained by administration of 6 per cent dextran in saline. In another group six dogs were nephrectomized after one or several venaectomies and still bled after the operation. The bleeding schedule was the same in both groups except in dog No. 37. The erythropoietic activity of the plasma was measured by iron ⁵⁹ red cell incorporation assay⁶ using starved female rats of the Long Evans strain. 6-10 rats were used for each determination. Different amounts of plasma were injected. Each rat received 2 cc of plasma from normal bled dogs subcutaneously daily for 2 successive days, and 6 cc daily when nephrectomized dog plasma was assayed. This larger quantity of plasma was used in order to rule out the presence of small quantities of erythropoietic factor. It has been shown⁷ that no erythropoietic activity could be demonstrated in plasma of anemic dogs by daily injection of 2 cc of plasma when hematocrit was higher than 12 per cent and erythropoietic factor level relatively low.

In Figs. 1 and 2 the relation is shown between hematocrit measurement of bled dogs and effect of corresponding plasma on red cell iron ⁵⁹ uptake of

Fig. 2. Values of erythropoietic activity of plasma from bled dogs before and after nephrectomy with regard to corresponding hematocrit.

Table 1 EFFECT OF ANÆMIC DOG PLASMA BEFORE AND AFTER NEPHRECTOMY ON RED CELL IRON 59 UPTAKE OF THE STARVED RAT

| Dog No | Hematocrit % before nephrectomy | Quantity injected plasma daily (c.c.) | Control* | Before nephrectomy | After nephrectomy | | | |
|--------|---------------------------------|---------------------------------------|------------|--------------------|-------------------------|------------|------------|-----------|
| | | | | | 3 hr | 6 hr | 11 hr | 24 hr |
| | | | | | per cent iron 59 uptake | | | |
| 47 | 14 | 6 | 35 ± 0.08† | 12.9 ± 6.9 | 9.5 ± 6 | 5.5 ± 1.8 | 5.1 ± 2.6 | 4.1 ± 1.4 |
| 48 | 9 | 6 | 6.1 ± 3.8 | 16.4 ± 8.8 | 16.5 ± 5.2 | 13.8 ± 8.7 | 11.0 ± 6.2 | 5.5 ± 2.9 |

*Control normal plasma injected before bleeding and before nephrectomy

†Standard deviation

starved rats Fig 1 illustrates the increased iron-59 uptake when severely anæmic dog plasma was injected into the rat. When nephrectomy was carried out no further erythropoietic activity could be demonstrated in the plasma 24 hours later in spite of increased anæmia (Fig 2). Plasma from 2 dogs (47 and 48) assayed 3, 6, and 11 hours after nephrectomy (Table 1) show the very rapid plasma disappearance of the erythropoietic stimulating factor. These results suggest that suppression of erythropoiesis in nephrectomized dogs results from a lack of erythropoietic factor and supports the evidence that the kidney is the source of this factor. It seems unlikely that after nephrectomy intoxication of another site of erythropoietic factor production occurs when erythropoietic stimulating activity disappears in such a short time as 6–24 hours after nephrectomy. Normal erythropoiesis in ureter-ligated dogs with comparable azolæmia also supports this view.

Another hypothesis compatible with these data is that the kidney normally destroys an erythropoietic factor inhibitor. To date removal of organs other than the kidney has not been shown to reduce the erythropoietic response to hypoxia.

This study is based on work performed under contracts with the United States Atomic Energy Commission.

A New Method for Studying the Functioning of the Lungs

In 1953 a gas in an aqueous solution, injected intravenously was used for the first time in studying the functioning of the lungs¹. It was later shown that all acetylene so injected was eliminated rapidly through the lungs. About 40 per cent was eliminated in the first minute by a healthy person. If the concentration of acetylene in the expired air was registered continuously by means of a special infra-red spectrophotometric method a direct determination of the interval between the commencement of the injection and the initial appearance of acetylene in the expired air could be made. This is probably the most accurate method for measuring the time of circulation from the site of the injection to the lungs. The acetylene elimination capacity was specially low in the presence of extensive pulmonary fibrosis, elimination of the gas was also retarded during an asthmatic attack.

Acetylene is, like carbon dioxide, very soluble in water. For respiratory studies it is, however, also of interest to study the elimination rate of gases with low solubility in water, especially if one wishes to investigate the rate of diffusion of the gases from the lung capillaries to the alveolae. Noble gases are especially good as radioactive tracers for this purpose as they are completely eliminated from the body in a short time. The diffusion of a gas through the lung membranes according to well-known physical laws, is directly proportional to the solubility of the gas in water and inversely proportional to the square root of its molecular weight. The diffusion rate for argon is accordingly about 40 times less than that for acetylene. The corresponding figure for xenon is about 20. The diffusion rates for argon and xenon are about the same as that of oxygen.

If acetylene and argon-41 are injected intravenously together, and the concentrations of the gases are continuously registered in the expired air, one would expect to find a retardation of the elimination of argon compared with that of acetylene, especially if difficulties of diffusion exist. The conveyance in the blood and the mixing of the gases in the alveolar-bronchial system will be equal in both gases.

Since September 1958 about 30 experiments have been performed with combined injections of acetylene and radioactive argon or xenon in a saline solution. Noble gases in small quartz bulbs were irradiated in a pile. The injections were performed in the cubital vein. 30 ml were injected in 2 seconds with an automatic syringe driven by compressed air. The radioactivity in the syringe was measured just before the injection. As the half life for argon is short, it is necessary to make a correction for this. The concentrations of gases, both acetylene and argon, were measured simultaneously in the same cuvette of an infra-red spectro-photometer. A sodium iodide scintillator is placed close to the cuvette. The spectrometer is supplied with a pulse-height analyser. The concentrations of the gases are registered on a kymograph of the mingograph type. After passing the cuvette the expired air is collected in rubber bulbs.

Figs 1 and 2 show the gas elimination in 2 persons, one with normal lungs and one with sarcoidosis in the lungs. The latter patient had only slight breathing difficulties during exercise.

From Fig 1A we can see that the greatest intensity of both acetylene and argon is reached after about 10 seconds. In Fig 1B the greatest intensity for acetylene is reached after about 11 seconds but that for argon is not reached until after 16 seconds.

The amounts of the gases eliminated, expressed as percentages of the amounts injected, were determined by collecting expired air for different periods of time in bags and analysing it. The values obtained for the two persons mentioned are shown in Fig 2. It shows that the person with normal lungs eliminates both gases at the same rate (Fig 2A). The person with sarcoidosis in the lungs, however, eliminated argon

Fig. 1 (A) Person with normal lungs. (B) Person with lung sarcoidosis. Abscissa, Time in seconds. Ordinate, acetylene concentration (on a logarithmic scale) and the counting rate for argon (on a linear scale). The top intensity for acetylene corresponds to an acetylene concentration of 0.15 per cent, the top intensity for argon to a counting rate of 1,500 c.p.m. (The initial curve deflections at time 0 depend on electric signals from the apparatus and are independent of gas concentrations.)

RADIOBIOLOGY

Fate of Injected Dextran Labelled with Tritium in Mice

THE metabolism of the blood plasma substitute dextran has been widely studied during the last decade. It was early shown that starch-splitting enzymes do not break down dextran but Grunwall found evidence that dextran is altered in the tissues to make it stainable with leuco fuchsin without previous treatment with periodio acid. Cargill and Brunner² showed that dextran labelled with carbon 14 is metabolized in mice since $^{14}\text{CO}_2$ could be recovered from the expired air and labelled carbonates isolated from the urine.

Several authors²⁻⁵ have found by using histochemical methods that part of intravenously administered dextran is stored in various organs and chiefly in the reticulo-endothelial system. Engstrand and Åberg⁶ showed that dextran is eliminated at least to a certain extent via the gastro-intestinal tract. This was later confirmed in a report by Troell and Åberg⁷. On the other hand, Burson and Bloom⁸ found no evidence of gastro-intestinal excretion of dextran.

Due to the controversies in the literature, we decided to tritiate dextran and to follow its distribution in mice autoradiographically after intravenous administration of the labelled product.

The following dextran preparations were used (kindly placed at our disposal by Pharmacia Ltd, Uppsala, Sweden):

- (1) Clinical dextran (mean mol. wt., 78,000 minimum mol. wt., 39,000)
- (2) Mean mol. wt., 197,000 minimum mol. wt., 133,000,
- (3) Mean mol. wt., 457,000 minimum mol. wt., 177,000

The tritiation was performed according to Wilzbach's method⁹. 100 mgm of dextran was exposed to 1 μ of tritium gas in a glass ampoule for 3 weeks. After tritiation the dextran was repeatedly dissolved

more slowly than acetylene in the first two periods of 10 seconds (Fig. 2B).

We believe that this difference can be used as a measure of impaired diffusion between capillaries and alveoli. The transport in the blood and the mixing of the gases in the alveolar bronchial system will be equal for both gases. Experiments are being continued on and different lung diseases are being investigated on these lines.

in 100 ml of distilled water and precipitated with ethanol

The specific activity of the tritiated dextran was 15.2–5.1 mc per gm dextran

The tritiated dextran was dissolved in water to give a final concentration of 6 per cent. Of this solution 0.3 ml was injected intravenously into a tail vein of white mice weighing about 25 gm. The animals were killed after 5, 30, 60 and 90 min and after 6, 24 and 48 hr. Autoradiography was performed according to Ullberg's method¹⁰. This method gives sections of the whole animal and dextran is not lost from the sections.

In order to check the stability of the tritium label, the following experiment was performed. A mouse was given tritiated dextran intravenously, the urine was collected during the following 4 hr and the urinary dextran precipitated with ethanol. After centrifugation, the radioactivity of the supernatant and the precipitate was measured. It was found that 96 per cent of the activity was present in the precipitate.

Thirty minutes after the injection of dextran, the autoradiograms show an accumulation of radioactivity in liver and spleen and an excretion into the gastrointestinal tract and via the kidneys. The radioactivity in the blood decreases fairly rapidly. In the spleen the dextran is localized to the marginal zone of the white pulp (Fig 1). In the liver the dextran seems to be confined to the reticulo-endothelial cells. No radioactivity is visible in the bile. The kidneys show high radioactivity especially during the first hour after the administration.

In Fig 2 the distribution of dextran is shown autoradiographically 24 hr after administration. The greatest part of the activity is contained in the liver. Radioactivity is also found in the intestines and the spleen (not shown in Fig 2) but the activity is considerably less than that of the liver.

Fig 1 Autoradiogram showing the distribution of tritiated dextran in a mouse 90 min after intravenous injection. White areas correspond to high dextran content. Note high activity in stomach, liver and spleen.

When the various fractions (1–3) are compared, it appears that the excretion, especially into the gastrointestinal tract, is higher for fraction 1 having the lowest mol weight. The different fractions however,

Fig 2 Autoradiogram showing the distribution of tritiated dextran 24 hr after intravenous injection. White areas correspond to high dextran content. Note high activity in liver and intestines.

show about the same accumulation in the liver and spleen. A detailed report will be published later.

Removal of Strontium and Cesium from Milk

THE appearance of radioactive isotopes of strontium in the food chain has caused considerable concern. There is complete agreement that these isotopes constitute a hazard to health, but controversy about the quantitative aspects of this hazard.

Milk is one of the most important dietary sources of the strontium isotopes. Reduction or elimination of these isotopes from milk may be a means of resolving the hazard.

It has been repeatedly observed by investigators studying bone metabolism that isotopes of calcium and strontium are removed from blood very quickly and appear in the skeleton^{1,2}. The heteroionic exchange with skeletal calcium accounts in large part for this rapid removal and does not result in a change in the net calcium concentration of the blood³.

With this exchange process in mind it was decided to try to remove strontium from milk by means of a cation exchange resin in a calcium form.

In 1954, Nervik, Kalkstein and Libby⁴ used a cation exchange resin in a sodium form which removed both calcium and strontium from the milk. This method would necessitate replacement of the calcium content. After the present work was started, a report by Glueckauf, Cosslet and Watts⁵ came to my attention. They employed an anion exchange resin in the chloride form to remove iodide, and suggested that radiostrontium could be removed by passing the milk through a cation exchanger bed,

which is regenerated with a mixture of calcium and sodium chloride

In the present investigation, 'Dowex 50H-A12 was employed. Experiments were conducted on commercial milk to which strontium 89 was added and on guinea pig milk containing strontium 89 diluted with cow's milk. The resin was treated with a solution of 18.0 per cent calcium chloride, 15.5 per cent potassium chloride, 6.5 per cent sodium chloride. The ratio of the cations in this solution is the same as that which exists in milk. 50 gm of the resin was stirred for 30 min with five successive 200 ml portions of the salt solution. Table 1 shows the efficiency of this resin for removing strontium from milk.

Table 1. EFFECT OF CALCIUM-POTASSIUM-SODIUM RESIN TREATMENT ON REMOVAL OF STRONTIUM 89 AND CATION COMPOSITION OF MILK

| Amount resin per 20 ml milk (gm) | Calcium (per cent) | Sodium (per cent) | Potassium (per cent) | Strontium-89 removed (per cent) |
|----------------------------------|--------------------|-------------------|----------------------|---------------------------------|
| 0 | 0.120 | 0.018 | 0.105 | |
| 0.25 | 0.127 | 0.031 | 0.105 | 63.5 |
| 0.50 | 0.126 | 0.019 | 0.101 | 76.8 |
| 1.00 | 0.128 | 0.050 | 0.101 | 80.7 |

Note—Strontium-89 content of milk was 6.75 µg./100 ml

Table 2. EFFECT OF CALCIUM-POTASSIUM-SODIUM RESIN TREATMENT ON REMOVAL OF CESIUM FROM MILK

| Amount of resin per 20 ml milk (gm) | Cesium removed (per cent) |
|-------------------------------------|---------------------------|
| 0.25 | 50.1 |
| 0.50 | 56.6 |
| 0.75 | 60.6 |
| 1.00 | 75.8 |

The analyses of milk before and after treatment are also shown in Table 1. The results indicate that no change is produced in the calcium, potassium or sodium content of the milk and 80.0 per cent of the strontium has been removed by one treatment with resin. A taste panel could not detect any change in flavour of the milk as a result of the resin treatment.

Milk obtained from guinea pigs previously injected with strontium 89 and diluted with cow's milk was also treated in the same manner. The percentage of strontium removed was the same.

An experiment was carried out with milk to which cesium 137 was added. The results shown in Table 2 indicate that cesium 137 is removable by means of the same resin which removes strontium.

The indications are that removal of strontium and cesium from milk is feasible without altering the milk. The question remains whether the process could be placed on a commercial basis if it ever became necessary; the answer can best be obtained by co-operative effort among the organizations concerned with this matter.

I thank Mr F. Pheasant for his assistance and Dr D. F. Coffin and Mr S. M. Skinner for analyses of the cations in the milk.

In Vitro Labelling of Antibody Globulin by Tritium Exchange

CRAWFORD L. Hawkins and Smyth¹ have reported the preparation of tritiated antibody by biosynthesis. The report of successful labelling of lysozyme and ribonuclease by *in vitro* tritium exchange² suggested that antibodies might also be amenable to tritiation by the latter method which has the advantages of simplicity, larger yields and usually results in products of sufficiently high specific activity to permit their use as reagents in radioautographic studies.

We have found it possible to label γ_2 globulin prepared from antisera against the Ehrlich mouse ascites carcinoma in this manner. Specific activities varied between 1 and 10 mc/gm of protein depending on the time of exposure to tritium gas (one to two weeks). Labelling was carried out both in the dry state at room temperature and in solution at 5°C, degradation products were formed to the approximate extent of 5 per cent of the original protein in the case of the first method and 15 per cent in the case of the second. Subfractionation of the labelled globulin by chromatography on DEAE cellulose revealed some changes in the distribution of combining activity between peaks; the combining activity of the whole labelled globulin however was unchanged as estimated by the quantitative complement fixation test. Ultracentrifugal studies showed a tendency toward separation of the original major peak of the unlabelled material into two peaks after labelling. Observation of the fate of the labelled material in the bloodstream of the rabbit yielded no evidence of change in the direction of antigenicity and there was no increase of any consequence in the rate of elimination.

It is concluded that labelled antibody globulin may be prepared by *in vitro* exchange with tritium gas without loss in titre and without major changes in physical properties. It is therefore possible that tritiated antibodies may find application in localisation studies using the radioautographic technique.

A detailed report of this study will appear elsewhere.³ This research was supported by a grant from the Michigan Memorial Phoenix Project.

BIOLOGY

An Embedding Resin Miscible with Water for Electron Microscopy

THERE are three embedding media commonly used at present to prepare biological specimens for thin sectioning and electron microscopy: methacrylate esters,¹ Vestopal polyester resin² and 'Araldite' epoxy resin.³ These although excellent for many purposes all have the limitation that they are not miscible with water and so require the specimen to be

dehydrated before it can be infiltrated with the medium. This dehydration, for which ethanol is most often used, frequently causes undesirable leaching of tissue components. The introduction of a water-miscible resin of low solvent power therefore appears desirable.

Several commercial epoxy resins approach these requirements but none is completely miscible. A suitable resin ('Aquon') has therefore been prepared by extracting the completely miscible fraction of a partially miscible commercial resin, 'Epon 812' (Shell Chemical Corp., 380 Madison Ave., New York 17). A solution of 'Aquon' was obtained by extracting 'Epon 812' with two volumes of water. The resin was crudely separated from this solution by salting it out with sodium sulphate. Residual water was removed by drying in a vacuum desiccator. The yield obtained was about 30 per cent. The resin, kept dry, has proved stable over a period of six months.

Prepared in this way, 'Aquon' resin is a colourless hygroscopic liquid of fairly low viscosity ($\eta \sim 100$ centipoises at 25°C). It is completely miscible with water at temperatures below about 15°C , at slightly higher temperatures it is only partially miscible.

When treated with a suitable hardener and accelerator 'Aquon' cures, without appreciably shrinking, to a solid resin that can easily be thin sectioned by conventional methods. A suitable mixture is 10 ml 'Aquon' resin, 25 ml dodecyl succinic anhydride (National Aniline Division, Allied Chemical and Dye Corp., 40 Rector St., New York 6), 0.35 ml benzyl dimethylamine (Sumner Chemical Corp., 6 East 45th St., New York 17). Heating the mixture to 60°C for four days provides an adequate cure.

The following procedure has been used for embedding. The fixed and washed specimens were slowly dehydrated by passing them through a series of increasingly concentrated cold (4°C) solutions of plain 'Aquon' resin in water. When they had been completely dehydrated by soaking in dry 'Aquon' resin the specimens were transferred to the complete embedding mixture given above. After about four hours for soaking, they were transferred to fresh embedding mixture in dry gelatin capsules and placed in the oven to cure.

Thin sections were prepared with a Porter-Blum ultra-microtome fitted with a glass knife and a trough of distilled water, those showing a silver interference colour were easily obtained. The sections were slightly softened, but not dissolved, by the water in the trough. Suitable staining for either light or electron microscopy was readily accomplished without removing the embedding medium.⁴

In trials 'Aquon' resin has been used to dehydrate and embed osmium tetroxide fixed specimens of pancreas, retina, and testis, bacteria (*E. coli*), and plant root tips. Comparison specimens have been prepared firstly by dehydration in ethanol and embedding in 'Aquon' resin and secondly by dehydration in ethanol and embedding in 'Araldite' epoxy resin. In most cases the general quality of preservation in the test specimens dehydrated in 'Aquon' appeared very good and equal to that in the control preparations. The characteristic organization of the centrioles, granular and agranular cytoplasmic membranes, mitochondria, nuclei, and retinal rod cells appeared substantially the same in all cases, further work is required to decide whether any significant differences occur.

It is considered that an embedding resin miscible with water will be valuable in cases where it is

desired to avoid subjecting specimens to conventional dehydrating agents with their strong solvent power. The range of applications in which practical benefits will be obtained from this technique remains to be determined. Preliminary experiments have indicated that specimens fixed with formaldehyde show substantially improved preservation.

Epoxy compounds in aqueous solution are known to react readily with proteins and nucleic acids^{5,6}. Poly-epoxides, such as 'Aquon' resin, introduce intermolecular cross-linkages, they will therefore tend to act as fixatives and aid in the preservation of structure. This fixative action, although probably insufficient by itself for adequate preservation of the tissue as a whole, may be important in preserving structures rich in nucleic acids, with which other common fixatives do not react.

Full experimental details of this work will be reported elsewhere. The greater part of the work was carried out at the Johnson Research Foundation of the University of Pennsylvania and was supported by a grant from the National Science Foundation to Dr T. F. Anderson, to whom I am grateful for his interest and encouragement.

8-Azaguanine Inhibition of Hæmoglobin Synthesis in De-embryonated Chick Blastoderm

THAT an important relationship exists between nucleic acid metabolism and protein synthesis is well known. The addition of some analogues of nucleic acid components to developing systems has been shown to result in abnormal growth, differentiation or cell division, which it is assumed are due to an interference with normal protein synthesis. Investigations concerned with the effect of nucleic acid analogues on the formation of a specific protein have been restricted mostly to micro-organisms^{1,2}.

The following report summarizes the development *in vitro* of a simple vertebrate histogenic system in which the appearance of a specific protein, hæmoglobin, is studied in the presence of the nucleic acid base analogue 8-azaguanine and of the normal component guanine.

The chick blastoderm at approximately 20-hours incubation is removed from the egg and transferred to a watch glass containing fluid albumen³ where it undergoes further development. At the stage required the embryo proper is excised from the middle of the blastoderm and the remainder of the blastoderm is washed and transferred to an agar gel. This step serves to block cell migration entirely and growth very considerably in the ectodermal and endodermal layers, leaving the mesodermal blood islands unaffected in respect to both cell division and differentiation. The primitive erythroblasts multiply, synthesize hæmoglobin and ultimately form primitive erythrocytes contained within ill-defined tubular endothelium.

The development of hemoglobin is observed microscopically both directly as a red colouration in the blood islands and indirectly with the more sensitive and stable haemoglobin peroxidase reaction with o-dianisidine. Within the system described this peroxidase reaction is specific for cells of the blood islands and, as indicated by colorimetric and electrophoretic tests specific for hemoglobin.

nucleic acid associated reactions are involved in this particular protein synthesis, they are much more responsive to analogue inhibition before, than after stage 9 by which time the synthetic pathway has become established.

Of further interest is a series of experiments which locate the end point of this period in a relatively narrow zone on the developmental time scale. In this

series there are two categories: (1) the de-embryonated blastoderm is first incubated on $N + Az$ gel for a certain time then transferred to A (Fig. 1, $Az \rightarrow N$); (2) the de-embryonated blastoderm initially incubated on A gel then transferred to $Z + Az$ gel (Fig. 1, $N \rightarrow Az$).

In all cases where hemoglobin appears there is some inhibition though the time of appearance is much the same as in the earlier series. Prior to stage 8 no hemoglobin develops if de-embryonated blastoderm are first placed on $N + Az$ gel (minimum period in these experiments 1 hour). If however they are first placed on N gel for a period such that they reach the equivalent (in time) of developmental stage 9 before contact

with azaguanine hemoglobin will develop.

This effect is most apparent when blastoderms de-embryonated at stage 8 are studied in more detail: (1) One hour exposure to azaguanine in only system prior to stage 8 blocks hemoglobin synthesis but not at stage 8 or beyond; (2) Two hours exposure at stage 8 will delay while (3) three hours will block the appearance of hemoglobin although some nuclei now show a positive peroxidase reaction. If a stage 8 blastoderm is first incubated on A gel and then transferred to $N + Az$ gel then (a) two hours on the former is insufficient for hemoglobin development; (b) three hours results in the system producing some hemoglobin; (c) four hours results in almost normal hemoglobin synthesis.

Comparing (1) and (2) with (a) and (3) with (b) and (c) these experiments suggest that there is a period of only a few hours prior to stage 9 that is critical to the final synthesis and production of hemoglobin when that synthesis is being blocked by 8 azaguanine. It is about this time that the peroxidase reaction becomes positive in the nuclei of single erythroblasts and in small groups of nuclei scattered within the blood islands.

This study of hemoglobin synthesis during the simple *in vitro* histogenesis described above leads to three conclusions:

(1) The nucleic acid base analogue 8 azaguanine (10 mgm/100 ml) will block hemoglobin formation before but not after a period during which some part of the synthetic pathway or perhaps some ribonucleic acid associated structure is forming.

(2) This period is of two to three hours duration and occurs just before developmental stage 9 on the Hamburger and Hamilton scale.

(3) The erythroblast nuclei rather than the cytoplasm show the first evidence of haemoglobin synthesis.

Fig. 1. Columnal indicate the developmental stage of transfer to gel medium. (1) Head region; (2) Head fold; (3) Somite; (4) (5), (6) and (10) 2×4 and 10- μ (Hamburger and Hamilton). Areas subdivided into hours. Each set represents a particular treatment. $N + Az$ represents the transfer to a buffered saline glucose-azur gel. $N + Az$ gel contains 8-azaguanine (10 mgm/100 ml.) in addition to the constituents of the N gel. $N + Az + G$ contains guanine (10 mgm/100 ml.) as well as 8-azaguanine (10 mgm/100 ml.) ($N \rightarrow Az$). In this set the de-embryonated blastoderm is first placed in a gel containing 8-azaguanine. After a certain time it is transferred to an A gel ($Az \rightarrow A$) the preceding treatment reversed.

Matograms show the time of appearance of hemoglobin in hours from plating in the gel in the first three sets and from the transfer to the second set in the last two sets. Row (Ib) indicates the extent of hemoglobin development at 48 hours and row (0-48) the hemoglobin peroxidase activity at 12 hours, after transfer to the final gel. The values to be interpreted as follows: (a) No visible pigment or reaction in cell groups, cytotelomeres or nucleus; (1) A few scattered, small isolated faintly pigmented blood islands or isolated single nuclei and small groups of nuclei peroxidase positive; (2) blood islands interconnecting some interconnected but pigmentation still faint; peroxidase reaction more intense and reticular appearance well defined; (3) Deep red pigmentation clearly visible to naked eye. Intense and extensive peroxidase reaction in both cytotelomeres and nucleus. Blank space indicates no reaction. Row (No) refers to the number of embryos used in row (Ib). In row (0-48) two embryos were used in each case.

Fig. 1, A demonstrates the synthetic *in vitro* of hemoglobin by the blastoderms de-embryonated at developmental stages 5 to 8 (Hamburger and Hamilton scale) transferred to agar and incubated at 37.5°C for 48 hours. Blastoderms incubated for 12 hours were used for peroxidase reactions. At this time hemoglobin was only just microscopically visible (level 1 Fig. 1) in isolated small groups of cells.

The presence of 8 azaguanine (10 mgm/100 ml.) effectively blocked the appearance of hemoglobin (Fig. 1, $N + Az$) in all systems set up before the entire blastoderm had developed to stage 9. Stage 8 systems gave a faint positive peroxidase reaction but did not develop visible hemoglobin.

Guanine at the same concentration and in the presence of 8-azaguanine (Fig. 1, $N + Az + G$) relieved the block completely except in stage 5 where inhibition still remains. In systems set up at stage 9 and beyond, haemoglobin synthesis was unaffected by azaguanine in concentrations of 10 mgm and 20 mgm per 100 ml and histological examination showed normal erythrocytes to be present in the blood vascular spaces.

These results demonstrate that whatever ribo-

Pyrethrum Resistance conferred by Resistance to DDT in the Blue Tick

IN a general investigation of the effectiveness of pyrethrum formulations for the control of a variety of species of cattle ticks in South Africa, a laboratory study of the effect of pyrethrum on the blue tick, *Boophilus decoloratus* Koch, was undertaken.

The blue tick from some localities of South Africa has developed resistance to a number of insecticides. A study of the pattern of cross resistance using a number of insecticides has shown that resistance in the blue tick is of three distinct types (a) to sodium arsenite, (b) to γ -BHC and related compounds, and (c) to DDT and its analogues¹. The types of resistance may occur singly or in combination.

Results of an examination of the effect of a pyrethrum formulation applied to three strains of adult blue ticks by an *in vitro* immersion technique¹ are shown in Fig. 1. The formulation concentrate con-

Per cent concentration of pyrethrum ($\times 10^{-4}$)

Fig. 1 The effect of pyrethrum on three strains of the adult female blue tick. The formulation concentrate contained 10 per cent pyrethrin, and was made by diluting pyrethrin extract (25 per cent) with aromatic solvent, adding 10 per cent of a proprietary blend of anionic/nonionic emulsifier to render the formulation dispersible in water. It was used freshly-prepared, obviating the need for stabilising materials.

The results indicated that the arsenic-BHC-DDT resistant strain was more tolerant to pyrethrum than was the sensitive strain or the strain resistant solely to the BHC group of insecticides. Later it was possible

Fig. 2 The effect of pyrethrum on four strains of blue tick larvae. O, BHC resistant; Δ , AS BHC DDT resistant; \square , AS BHC resistant; X, sensitive strain. Probit of per cent mortality.

to examine four different strains of blue tick larvae in a technique designed to detect differences in response to a number of insecticides¹. The results of these tests are shown in the log dose-probit mortality curves in Fig. 2 (see also Table 1).

Table 1 THE DIFFERENCE IN RESPONSE TO PYRETHRUM BY DIFFERENT STRAINS OF BLUE TICK LARVAE

| No. | Strain of blue tick larvae | LC 50 pyrethrum concentration (per cent) | Factor of increased tolerance as compared with the most sensitive strain |
|-----|---|--|--|
| 1 | Resistant only to the BHC group of insecticides | 9.5×10^{-4} | 2.38 |
| 2 | Resistant to sodium arsenite, the BHC group and the DDT group of insecticides | 72.4×10^{-4} | 18.1 |
| 3 | Resistant to sodium arsenite and the BHC group of insecticides | 9.6×10^{-4} | 2.4 |
| 4 | Sensitive to all insecticides | 4.0×10^{-4} | 1.0 |

These results suggest that the blue tick resistant to BHC alone and resistant to BHC and sodium arsenite is slightly more tolerant to pyrethrum than the strain with no record of any insecticidal resistance. However, the increase in pyrethrum concentration required to produce 50 per cent mortality in these two resistant strains is comparatively low and is most probably a result of a difference in vigour.

The 18.1 fold increase in tolerance shown by the arsenic-BHC-DDT-resistant strain of larvae is too high to be accounted for by a general increase in vigour and suggests a definite biochemical resistance.

In houseflies, where the pattern of insecticide resistance is in many respects similar to that in the blue tick, there is no general cross-tolerance to pyrethrum conferred by resistance to DDT², although an Italian strain of flies resistant to DDT showed a clear cross-tolerance to pyrethrum³. It was not stated in this instance whether or not the Italian strain had been in contact with pyrethrum in the field at any time and under these circumstances the independent development of resistance to pyrethrum cannot be excluded. However, in South Africa the treatment of cattle with pyrethrum for the control of ticks on a field scale has never been practised and the only conclusion that can be drawn is that resistance to DDT confers a substantial cross-resistance to pyrethrum.

This work was undertaken in the Research Department of African Explosives and Chemical Industries Ltd with the collaboration of Cooper and Nephews South Africa (Pty) Ltd to which thanks are accorded for permission to publish the result

Organ Cultures of Total Mammary Glands of the Mouse

In the course of experiments on hormonal influences upon tissue cultures of normal and malignant mammary tissue, a difficulty was encountered that in the common tissue culture and organ culture methods the duct systems are cut or disturbed by other means, resulting in wound healing reactions of the epithelium. These reactions may interfere with the normal functions of the epithelium to hormonal stimuli.

Hardy² described the development of mammary glands from the anlage when culturing parts of the ventral body wall of 10-13 day mouse embryos. Her conclusion was that at this stage of development the differentiation of the mammary gland is not primarily dependent on specific hormonal stimulation. In the case of embryonic tissues independent developmental tendencies may obscure hormonal influences.

A method was therefore devised for cultivating whole mammary glands of mice beyond the embryonic stage. The third mammary glands of such mice are spread out in a flat thin flat pads offering favourable culturing conditions. In these experiments female *C57BL/6J* mice (*J1* hybrids *C57BL/6J* × *DBA/1*) six weeks of age were used.

The mouse is killed by breaking the neck spine. It is then immersed for a moment in 70 per cent alcohol to sterilize the skin. The integument is stripped off taking care not to damage the attached mammary apparatus. After extending it on a cork plate—made uppermost—the tissue overlying the third mammary glands is carefully removed. Next a piece of nylon gauze (nylon filter gauze as used in blood transfusion systems) is spread over each gland and a drop of cockerel plasma and one drop of chick embryo extract are put upon it in order to stick the gland to the gauze. This sticking prevents the gland from shrinking afterwards. The excess of fluid is sucked off. The plasma is allowed to clot during which period the whole is covered with a glass lid to prevent desiccation. Afterwards the gland plus the gauze are prepared loose from the underlying skin using very sharp knives of appropriate shape (Paragon scalpel blade No 17). All is done under normal aseptic precautions. If properly done, the only cut through the duct system of the gland is through the nipple.

Gauze and gland are then placed on the surface of a feeding medium gland tissue upwards. The medium is contained in a little cup formed by a stainless steel ring that has been immersed in melted paraffin wax and placed while still warm on a sterile glass plate; as the paraffin wax solidifies a cup is formed into which culture medium is pipetted. The bordering ring supports the nylon gauze. The whole is covered

Fig. 1. Part of first mammary gland of a 6-week-old mouse fixed at the first title experiment.

Fig. 2. Part of third mammary gland of the same mouse cultured for 13 days.

Fig. 3. Part of third mammary gland of the same mouse cultured for five days with the addition of progesterone by half a Petri dish sealed to the glass plate by paraffin wax.

by half a Petri dish sealed to the glass plate by paraffin wax.

The culture medium was a mixture of Tyrode (7 drops), mouse embryo extract (1 drop), human umbilical cord serum (2 drops) and horse serum (2 drops) with ± 500 u/ml penicillin added. This medium was devised for the culture of human mammary carcinoma and gives excellent results with mouse mammary glands although a less complicated medium might suffice for the latter. The quantity of nutrient in the cup (inside diameter 17 mm, height 3 mm) is sufficient for a five day culture period. For long term cultures it is advisable to renew the medium three times a week.

The accompanying illustrations are of a pair of third mammary glands of a mouse, one of these was cultured as described above (control). The other was cultured identically except that about 1 mgm of progesterone had been added. This progesterone had

been dried on to the nylon gauze from a solution of progesterone in acetone, before the gland was stuck to it

The control culture shows a regression in development compared with the first mammary gland that had been fixed at the beginning of the experiment. This is a regression, not merely a degeneration, a number of cells of the tubuli degenerate and die, the remaining cells remain in good condition and may survive for at least three weeks.

The control culture shows collapsed tubules but without signs of regression, there is possibly an increase in nuclear material. The cultures shown were fixed after five days in culture. These effects were found to be reproducible in four series of each one pair of experiments.

Full details of results obtained with several hormones will be published elsewhere.

An additional advantage of the method is that pictures are obtained comparable with the mammary gland preparations as used in hormone and cancer research in intact mice.

Speciation among Lampreys

Not all lampreys migrate to the sea. Some (the 'landlocked') always remain in fresh water, but after metamorphosis they migrate from the brooks, where they are born, to lakes and rivers. After a long feeding period they go back to the brooks, where they spawn and then die. This is known to happen with *Petromyzon marinus*, the landlocked form of which multiplied abundantly and spread widely in the Great Lakes of North America¹. The same phenomenon was recorded for *Lampetra fluviatilis* of Lakes Ladoga and Onega in the U.S.S.R.²

In other cases more differentiated forms of species have originated. These I would call 'paired forms' or 'paired species'. There are, in fact, related forms of lampreys (usually a couple), which are almost identical morphologically, while their biological features are quite different. One form, in the couple, after metamorphosis, feeds parasitically on other fishes, while the other does not take any food. Moreover, the former reaches sexual maturity after the feeding period, whereas the latter begins its maturation during metamorphosis.

So far, cases of paired species of this kind were known only in the genus *Ichthyomyzon* and *Lampetra*. Recently I have found another one in the Danube waters for the genus *Eudontomyzon*. The relationship among the paired species or paired forms are shown in Table 1.

In every case the non-parasitic forms can be found in the same river basin together with the parasitic forms, but they are confined to the upper zone. Sometimes, however, both forms can be caught spawning at the same time and place³.

The parasitic lamprey in the Danube does not migrate at all, unlike the parasitic forms of other paired species. The former always remains in the same streams where it lived as a larva and underwent metamorphosis, just as the non-parasitic forms of the other cases of paired species. This perhaps explains why the existence of these two forms has remained so far unknown.

The presence of paired lampreys in so many different localities raises the problem of their specific difference and of their origin. The most common opinion to-day is that each of the two paired forms is a 'bona species' and that the non-parasitic species originated from the parasitic one.

Some previous authors thought that the parasitic form had become non-parasitic through having come to live in a habitat where they could not find suitable hosts. Recently Young⁴ and Leach⁵ advanced the suggestion that this phenomenon is similar to that of the neoteny or pedomorphosis: gonads maturation has been anticipated, probably by action of anterior hypophysis⁶, thus inhibiting parasitism after metamorphosis. This fact seems to be confirmed by the recent capture of female ammocoetes with mature eggs and well-developed secondary sexual characters⁶.

The lampreys of the Danube suggest the existence of a gradual stage in this process of transformation. At first, they apparently kept within fresh-water boundaries, which allowed internal migrations. Later, they stopped these migrations in fresh-water also, though retaining their nutrition stage. Finally, either on account of nutrition difficulties or because of anticipated gonads maturity, they become non-parasite, breeding without nutrition after metamorphosis.

From the observations which, so far, have been made on the lampreys of the Danube, it may be concluded that from *E. danfordi* may have arisen a non-parasitic, but morphologically similar form, which I name *E. danfordi vladylori*. This lives in the upper part of the Danube. Perhaps *E. mariae*, with some morphological differences and living in Russian streams flowing into Black Sea as well as in some tributaries of the lower Danube (Prut and some others), has a similar origin, but this hypothesis needs confirmation.

BACTERIOLOGY

A Non-Gummy Chromogenic Strain of *Azotobacter vinelandii*

BECAUSE of the widespread use of *Azotobacter vinelandii*: Wisconsin strain O, in biochemical studies recent observations concerning colonial types obtained from transfers of this strain are worthy of more general knowledge. As many investigators have noted (private communications) cultures of this strain at times become more 'gummy' than usual, and their further use for physiological or biochemical studies is difficult. Although we have attempted in the past to isolate a non gummy strain by selection of colonies such efforts have been only temporarily successful.

A *vinelandii* strain O was streaked on modified Burks nitrogen free agar plates¹. Differences in colonial morphology were readily evident within 18 hr of incubation at 30°C, when colonies were examined with the low power of a compound microscope or within 48 hr, when colonies were examined with the unaided eye. Colonies were obtained which differed in size, gumminess or pigment production in proportions that depended on the origin of the culture. The stability of these colonial characteristics was checked by streaking the cells of a well isolated colony on a fresh agar plate: two colony types were chosen for further study.

A gummy colony type that did not elaborate a pigment was easily recognized during microscopic examination of colonies, since at a magnification of 100 individual cells could be seen to be well separated by a clear slime. A non gummy colony type was dense, yellow, and free of slime. Since a colony composed of both bacterial types was easily recognized, the selection of a pure culture of each strain was made only from colonies that were homogeneous by microscopic examination. After a limited number of streakings it was evident that a pure culture of each strain had been obtained. The non gummy variety henceforth to be designated strain OP produced a yellowish green fluorescent pigment that is characteristic of other strains of *A. vinelandii*. Each isolate grew readily in Burks's nitrogen free liquid medium in shake flasks and fixed nitrogen as shown by total nitrogen analyses by the Kjeldahl method. Shake cultures of strain OP did not become gummy, whereas those of the other strain did. Even after numerous transfers in liquid or solid media strain OP remained non gummy, and during frequent examination of isolated colonies no gummy colonies were observed. The two strains had cells with a similar size and form with peritrichous flagella. Both strains would be distinguished from members of the *Azotobacter agilis* group on the basis of cell size and mannitol utilization². A *vinelandii* strain OP, which resembles very closely the first culture of *A. vinelandii* to be isolated³ will be deposited with the American Type Culture Collection.

It is appropriate to mention again the frequent observations (private communications) that cultures of *Azotobacter* spp may carry contaminants which are not detected unless special care is taken to search for them. Winogradsky⁴ observed that cultures of *Azotobacter* spp were impure even with primary isolation from natural material because of the limita-

tions of the standard method of isolation by plating. In nitrogen free media contaminants unable to fix nitrogen remain latent until nitrogenous products are released by the *Azotobacter*. Microscopic examination of colonies on solid nitrogen free media may reveal contaminants as satellite colonies. The use of sugar free peptone media recommended by Burk and Burris⁵ is convenient to detect contaminants since these generally grow well in such media while the *Azotobacter* do not. Accordingly the isolation of a pure culture of *Azotobacter* is best carried out when colonies are selected by microscopic examination.

N,O-Diacetylneuraminic Acid and N-Acetylneuraminic Acid in *Escherichia coli*

DURING the course of an investigation of the biochemical and biological properties of endotoxins extracted from various Gram negative bacteria, chiefly several *Escherichia coli* strains we found and reported briefly¹ on the presence in some of these endotoxins of a material having the colour reactions of a sialic acid. The bacterial lipoproteins and lipopolysaccharides which yield this material were prepared by the phenol water extraction method of Westphal², separated from accompanying nucleic acid and exhaustively dialysed. The sialic acid is released from this large molecule only upon mild acid hydrolysis and we, therefore, proposed that it forms an integral part of the cell wall of these bacteria. Members of the sialic acid group had been found previously mainly in mammalian tissue. Barry and Goebel³ had reported the elaboration of a sialic acid like material, colominic acid by a specific strain of *E. coli*. Barry⁴ has since reported this to be a simple polymer of N-acetylneuraminic acid.

We now wish to report the isolation and identification of both N-acetylneuraminic acid and N,O-diacetylneuraminic acid in several strains of *E. coli*.

Washed living cells of *E. coli* O15:H15:H15⁺ contain a minimum of 1 per cent neuraminic acid on dry weight basis which is released optimally by hydrolysis in 0.1N sulphuric acid for 30 min at 80°C. Such hydrolysates neutralised with barium hydroxide, were freed of cations by passage over a column of Dowex 50 X 8 resin in the H⁺ cycle. The neuraminic acids were adsorbed from this effluent by passage over a Dowex 2 X 8 acetate resin. After washing with water, the column was gradually eluted with 2 M sodium acetate-acetic acid buffer at pH 4.8 and distilled water in equal volumes so as to yield a first-order relationship of volume to buffer concentration in the eluate⁵. The entire method is a modifica-

cation of that of Svennerholm⁷. The peak of resorcinol and *p* dimethylaminobenzaldehyde reactive material appearing at 0.4–0.5 *M* is composed of 40–60 per cent neuraminic acids with a small portion being the diacetyl compound and the remainder the *N*-acetyl derivative. Two other broad peaks are eluted which contain neuraminic acid in combined forms, probably as saccharic peptides or as nucleosides and nucleotides. These are being examined at present.

The two neuraminic acid derivatives are separable by paper chromatography in a number of systems. When the two components were compared in four different solvent systems with *N*-acetylneuraminic acid⁸ and *N*,*O*-diacetylneuraminic acid⁹ no separation from authentic material was seen. Fig. 1 is repre-

Fig. 1. Paper chromatographic separation of bacterial neuraminic acid (NANA) into *N*-acetylneuraminic acid (NANA) and *N*,*O*-diacetylneuraminic acid (NODANA). System: ethyl acetate-pyridine-acetic acid-water (5.5-1-3). Spray: *p* dimethylaminobenzaldehyde (0.5 gm) and trichloroacetic acid (5 gm) in 20 ml of 50 per cent aqueous ethanol plus 60 ml *n*-butanol.

sentative of these results in one system (ethyl acetate-pyridine-acetic acid-water 5.5-1-3). The solvent front has been run off the paper in order to enhance any subtle differences in mobilities.

The slow-moving component gives positive resorcinol and orcinol reactions, is direct Ehrlich positive, ninhydrin negative and reacts as an α -keto acid and a reducing sugar. The adsorption spectrum of the resorcinol pigment formed from this component is identical to that obtained with authentic *N*-acetylneuraminic acid-resorcinol pigment. Tests for hexosamines, 3-*O*-substituted hexosamines, pentoses, 5-methylpentoses and hexuronic acids are negative. It does not contain any detectable glycolyl substituent by the assay of Klenk and Uhlenbruck¹⁰ nor is it separable from authentic *N*-acetylneuraminic acid on paper chromatography in *n*-butanol-*n*-propanol-0.1 *N* hydrochloric acid (1-2-1)¹¹.

The faster component reacts as *N*-acetylneuraminic acid in all the above reactions and, in addition, contains an *O*-acetyl group which has been isolated as the hydroxamate¹² and found identical with authentic acetylhydroxamate on paper chromatography in water-saturated *n*-butanol. This component is found in varying concentrations after ion-exchange resin purification and is unstable in solution even at low

temperatures. It appears to degrade to the *N*-acetyl derivative.

Treatment of partially purified bacterial neuraminic acid mixtures (~30 per cent as *N*-acetylneuraminic acid) with the bacterial aldolase of Comb and Roseman¹³ causes a loss (50–60 per cent) in resorcinol reactive material which agrees quantitatively with the formation of puuvic acid as determined enzymatically with lactic acid dehydrogenase. An *N*-acetylhexosamine, which cannot be distinguished from *N*-acetylmannosamine by chromatography on borate treated paper¹⁴, is also produced by enzymic action.

As the endotoxins extracted by the phenol water method are lipoproteins and have been shown by Weidel and Primosigh¹⁵ to derive from the exterior, non-rigid portion of the wall, it is probable that no structural significance vital to the integrity of the cell can be assigned to the bacterial neuraminic acids as has been indicated for muicamic acid by Work¹⁶. Other possible functions such as bacteriophage attachment, virulence or *K* antigen specificity are attractive hypotheses only.

Recently, Barry¹⁷ has suggested a correlation of *K*1 antigen and neuraminic acid occurrence in *E. coli*. It should be noted, however, that the two strains found by us to date to have the highest neuraminic acid content are an O₁₁₁B₄ (*K*58) and an O_{2A} (*K* untypable). This point is being examined further.

Although the colominic acid producing *E. coli* reported by Barry^{3,4} has been found by us to yield an endotoxin containing neuraminic acid and thus presumably has neuraminic acids in its cell wall, the level present in its endotoxin is no greater than that found in the lipopolysaccharides extracted from either of the other two strains. We believe that *N*,*O*-diacetylneuraminic, or possibly both this compound and the *N*-acetyl derivative, exists as a structural component in the cell wall of certain bacteria. A survey is in progress to determine the validity of this point.

NUCLEAR POWER AND ITS DEVELOPMENT

SIR JOHN COCKCROFT is reported to have expressed the opinion on April 26 that in 1966 some 25 per cent of the requirements of the United Kingdom for electricity would be met by nuclear generation, 50 per cent by 1975 and 100 per cent by the end of the century. Questions asked in the House of Commons on June 8 indicate a disposition to allow political and social considerations to over-ride, if not distort, the technical and economic aspects, and there have been other attempts to make the effect on the coal industry the deciding factor in determining the development of nuclear power. The implications of technological change have been ignored, as has the effect of development on the cost of electricity supplied by nuclear power stations, which Sir Christopher Hinton stressed very strongly in his Axel Axelson Johnson Lecture delivered at Stockholm on March 15 1957.

In his reply on behalf of the Government, the Paymaster General was emphatic that the programme for the development of nuclear energy in Britain over the next few years was arranged after careful consideration, and it certainly could not be upset on any temporary considerations. An admirable broadsheet, 'Prospects for Nuclear Power' (No 431, March 1959), issued by Political and Economic Planning is well designed to remove misunderstandings and facilitate an objective approach to this problem, in which it is extremely difficult to separate at all sharply the technical and economic from the political and social elements. Although the broadsheet is particularly concerned with the world position and Britain's export prospects, it includes a lucid discussion of the impact of nuclear power which deserves to be widely read. The brief paragraph on the position in the United Kingdom points out that by 1966, when the dozen or so nuclear power stations required to supply the target capacity of 5 000-6 000 MW are in operation the cost of the electricity generated should be almost competitive with that from other types of power stations wherever sited, this answers the criticism implied in the questions in the House of Commons.

The broadsheet points out that by 1966 the nuclear power stations will be supplying a quarter of the electricity used in Britain and doing the work of 18 million tons of coal a year, and that it is estimated that the cost of generating electricity from the largest of the stations now under construction that at Hinkley Point, will be between 0.58d and 0.66d per kWh, compared with 0.53-0.64d for an up-to-date coal-fired plant. The cost of electricity from the largest station now being built is competitive with that from a high-efficiency coal-fired station built on the same site. Moreover, for the later stages of the present programme when all new generating plant may be nuclear Britain is considering types of reactor that will be cheaper to build and more efficient

to operate, as well as able to accept recycled plutonium to replenish the burnt fuels, and these types should produce electricity more cheaply than conventional plants. Two such reactors are the gas-cooled heavy water moderated reactor and the advanced gas-cooled reactor—an experimental version of the latter is already being built at Windscale.

These facts, which were essentially given by Sir Ian Horobin in moving the second reading of the Electricity (Borrowing Powers) Bill on January 20 sufficiently display the tendentious character of the question to which Sir Ian replied in Parliament on June 8. It should also be remembered that the high temperature gas-cooled reactor is to be studied at Winfrith Heath, and the sodium-cooled fast breeder reactor at Dounreay, both within the subsequent period in mind when reactors will be needed to take over an increasing proportion of the base load. From the Dounreay reactor, to be in operation this year, will come the data necessary to enable fast reactors using plutonium fuel to be integrated with existing thermal reactors. This will improve the burn up of natural uranium to somewhere near the theoretical limit. The reactor programme is also supported by large facilities for research and an extensive research programme while production and fuel processing facilities are also well developed in Britain, and capacities are sufficient to meet the needs of other countries. Lord Mills the Minister of Power, stated explicitly in the House of Lords on March 3 that the nuclear power programme for 1964 onwards had not yet been determined.

This position, however, needs to be set against the general background outlined in the PEP broadsheet which stresses too the dynamic nature of the energy position both nationally and internationally, and the way in which non-economic influences often determine the most economical way of meeting demands for energy. The great promise of nuclear energy is that with ample resources of uranium and thorium, and the high energy content of each ton of raw material which makes transport a negligible factor it will eventually provide all nations with an unlimited and virtually indigenous supply of energy at an economic cost. Although this lies well into the future, nuclear energy should make an immediate though modest contribution particularly in Europe.

The factors which limit this contribution must be carefully noted in an objective assessment of the situation. First for technical reasons nuclear fission reactors are only efficient when employed in large units. The large amounts of electricity produced from each nuclear power station can in the near future be generated at an economic cost only if they can be used to the maximum. This is only possible where electricity systems are fully developed in a grid network such as an industrial area provides.

Accordingly, nuclear energy is as yet unlikely to help under-developed countries, nor will it be suitable for some time for the direct production of heat where small units are normal. In Europe, where fossil fuels are expensive, nuclear energy should be competitive within the next ten years for what is called base-load operation, that is, power-stations operating virtually all around the clock feeding electricity into the grid.

The second factor is that small coal is particularly suitable for power-stations, and the proportion of small-coal production is continually growing as more coal is mined by mechanical methods. This coal can only be burnt efficiently in very large plants and its use is thus almost confined to power-stations. Criticism of Britain's nuclear-power programme arises largely from this fact that nuclear energy is suitable for the production of electricity only in the conditions to which the growing quantity of small coal is also suited.

The third factor is that production of electricity at a price competitive with conventional power only means an additional supply of electricity and not the introduction of a cheap new fuel. Electricity has its own particular advantages, and its use in Britain is continually growing, but it is not, at present costs, an economic substitute for other sources of energy for many purposes. The nuclear-power programme should enable those needs to be met more easily, but it will not obviate the need for other fuels for these purposes. Nevertheless, the development of nuclear energy holds great promise, and Britain's prompt start has given her an early lead in tackling the vast technical problems involved, and only the U.S.S.R. and the United States have programmes at all comparable in size to the British. Moreover, the British power programme, based on the gas-cooled natural-uranium reactor, is the only large-scale programme which is being carried out in a Western country, and the British type of reactor has been proved in operation, having supplied electricity to the grid for some two years.

Nevertheless, the survey in *Planning* of the prospects for British exports of nuclear power-stations and related fuel and equipment leads to the conclusions that the prospects for British firms to export reactors are not so bright as they were once thought to be. Nuclear power is indeed regarded as the most helpful long-term solution of the fuel problem in many European countries, and the principal countries are in a position to exploit nuclear power without too much difficulty. They possess the necessary scientific and technical skills and the capacity to build equipment, and they will therefore want to develop their own nuclear industry as fast as they can. They may buy one or two reactors from other countries, as Italy has done, in order to gain experience of operation and construction, but after that they will probably do more and more of the work themselves. They are unlikely to set up their own fuel-processing plant, partly because of expense and partly because most European countries have no uranium deposits and are unlikely to obtain uranium

without some control against the production of plutonium. France is the one country of Europe which will have a self-contained nuclear industry.

In the Scandinavian countries, and possibly in Spain and Portugal, competition is likely to be fierce, and although the Calder Hall power-station has impressed potential customers with the merits of the British type of reactor, steady and impressive publicity is required. Outside Europe, the first markets—for the next ten years at least—will be in Japan and India, but China is likely to be tied to Russian developments at first. Several countries in Latin America might prove customers for the British type of large power-station reactor.

Whether British or American power reactors are bought—and these are the only countries at present offering to sell power reactors and supporting the offer with a fuel service—the PEP broadsheet suggests that the future of the nuclear reactor export market is closely tied to a successful small reactor. A cheap small reactor similar to that for moderately powered gas-turbine and diesel-powered generating sets could transform areas which are now under developed. Here, since British efforts have been concentrated on the Calder Hall type, Britain is less favourably placed than the United States to design reactors for special conditions. Without the urgency of Britain's fuel problems, the United States has been able to experiment with a wide variety of types of reactor, and this could prove an important advantage in meeting the future export demand for a small and flexible reactor system. Besides this, the United States is at present the only country that can supply enriched uranium for reactors abroad.

Britain is now taking the preliminary steps to enable her to meet the demand for small reactors, but it is possible that the Soviet Union, although it has not yet been active in export competition, could also have an advantage over Britain in the matter of reactor types. Nevertheless, the broadsheet points out, reactors are not the only product that can be exported. The one part of the British power-reactor which is not manufactured by industry is the fuel element. The rest, including ancillary equipment, such as turbines, generators, handling gear, processing equipment and control instruments, are all the products of industrial firms. Lord Mills, it is true, has directed attention to the more limited opportunities in the near future for new consortia of firms with design teams trained by the Atomic Energy Authority and which would be capable of tendering for the construction of complete nuclear power-stations, but at the same time, he emphasized the opportunities for the manufacture of small reactors, including research reactors.

Nuclear energy, as the PEP broadsheet puts it, means that there will be an increased demand for those products which British firms can supply as cheaply as any of their competitors, but the prospects for British exports of nuclear reactors and equipment are not determined solely by the competitive ability of British firms. One dominant factor will be the political agreements that the Government

is able to make Marketing nuclear reactors is not purely a commercial undertaking, for, as the broad sheet duly notes international politics are involved and unless this is clearly understood British chances of building up an export trade will be small.

For this reason alone it is important that Britain should establish close and satisfactory relations both with the International Atomic Energy Agency and the European Organization for Nuclear Research and also with Euratom—the European Atomic Energy Community and its six members. A second factor however to which Planning does not direct attention is that of scientific and technical man power. Although in the stricter sense this lies outside the scope of the broadsheet, it is probably the ultimate factor on which the prospects for British development of nuclear energy depend. Unless the resources of scientific and technical man power in Britain are fully developed and effectively used, Britain is unlikely to be able to seize the opportunities that nuclear energy will bring—even to secure all the advantages which its development in Britain might offer to the economy of the country—still less to hold her own in the keen competition forecast in this broadsheet. Nor is this simply a matter of training sufficient scientists and technologists: it is also a matter of seeing that they are wisely used that our organization and administration of research are adequate and in balance and that the administrators and statesmen called upon to handle the complex and interlocked technical, economic and social problems which the development of nuclear power will bring are competent to give due weight to all the scientific and technical issues no less than to the economic or political aspects of the situation.

For some months Euratom experts have been drafting a new and realistic programme for the six member countries, taking account of changing oil and coal prices. Since the PEP broadsheet was issued, the report on this programme has been finished, but owing to disagreement at the top it has been withheld and is not to be published. This disagreement has jettisoned Euratom's plans for all but the 1,000 megawatt programme being carried out with American aid, and it is obvious from the broadsheet that most of the chances open to British industry of tendering for foreign nuclear power stations have likewise disappeared.

Sir Ian Horobin took a far more confident view in replying in an adjournment debate on the nuclear power programme in Britain in the House of Commons on July 1. He confirmed that latest figures gave the cost of electricity from conventional stations as 0.5-0.65d a unit compared with 0.65-0.7d for electricity from nuclear power stations, but he emphasized that the statement that nuclear energy to day is 40 per cent more expensive than conventional power was based on a comparison of the cheapest possible coal and the dearest existing nuclear energy. Sir Ian suggested that the real difference is probably more like 15-20 per cent and he pointed out that in view of the 70 per cent rise in the price of coal over the past ten years it would have been

unrealistic to base policy on the assumption that coal would not be 5-7s a ton dearer than it is now. He also thought that the price of uranium will fall when the present contracts expire and that this factor with a further slight rise in the price of coal, is likely to decrease the margin of 15-17 per cent against nuclear energy, and that the price of generating electricity by nuclear energy is likely to touch that of generating by coal in the late 'sixties.

Sir Ian Horobin insisted that the British nuclear power programme is a very carefully considered whole and that it is probable that what may be called the Calder Hall type of reactor has several years of valuable development before it. About 1961 the advanced gas-cooled reactor should become critical and if this is successful the first commercial type may be in operation about 1965. The work done with the fast breeder reactor now being developed at Dounreay has been very successful and a period of low power testing at Dounreay is expected to begin this summer. If all goes well we may hope to have this type in operation by about 1970, and its low capital cost and its place in the balanced programme offer exciting possibilities particularly in flexibility. By that time a substantial number of stations of the Calder Hall type would be in operation all producing plutonium. We must bear in mind Sir Ian said, the possibility of a situation arising when it would be possible to build very much larger stations than originally conceived and that perhaps only about half a dozen more stations would come into the programme. He repeated that we cannot afford to run any risk of completely unbalancing the structure of the industry in Britain by interfering with the present programme. When that programme is complete further decisions will be required and although preliminary consideration is being given by the Government to the subject, it is not thought that it is necessary to decide for a further year or two what stations should be built after 1965. It is very important he said that everyone should realize that a nuclear power programme on the scale of that in Great Britain must be a long term, carefully balanced programme and that it cannot be interrupted in response to short term considerations. Britain is now the major civil nuclear power, and the need for thought and care in investment and design are correspondingly great.

DARWIN WITHOUT MODERN SCIENCE

Darwin and the Darwinian Revolution

By Dr Gertrude Himmelfarb Pp ix+422. (London Chatto and Windus Ltd 1959) 42s net

AN adequate study of Darwin his scientific achievements and the result of his work in all the fields of human endeavour which they have affected makes rigorous demands on the competence of whoever attempts to write such a book. Dr Himmelfarb brings to her task a concentration of interest and of effort, the former of which is passed

on to the reader by the sustained vigour and elegance of her style and the skill with which the book is constructed, while the mastery of her technique hides the laboriousness of the work involved.

She has read practically everything there is to read by Darwin and on Darwin, including manuscripts hitherto unpublished, and has subjected the material to lucid analysis in terms of the history of Darwin's life, experiences, contacts with other persons, researches, results, doubts and beliefs. He is situated in his intellectual environment, his home life, his ailments real or imagined, and his place in history. The social, scientific, religious, political and general public climates of his day are vividly portrayed, and there can seldom have been a work of biography undertaken with such bibliographical care.

But while it would be difficult to exaggerate the excellence of this book as a contribution to the history of the events, ideas and arguments as a result of which Darwin produced his theory of evolution by natural selection, the case is altered when it comes to the evaluation of this theory in terms of the present state of scientific knowledge, because Dr Himmelfarb's work is imbued with a relentless aversion to natural selection, pursued by means of a skilful and acute dialectic without reference or regard to the results of scientific research during the past fifty years. Indeed, this is directly implied by the statement (p 366) that "the present status of Darwinism has not altered much since 1860, when Huxley pronounced it to be not an established theory but a tentative hypothesis". When she tries (p 368) to substantiate such a view to-day by quoting William Bateson, she gives herself away at once.

That the author is not familiar with, or prefers to ignore, the growing edge of scientific knowledge by observation and experiment during the past fifty years appears from statements such as the following (p 269) "In the experiments of Mendel and de Vries, new species appeared suddenly in the form of mutations". Mendel neither claimed nor obtained any such results. On the contrary, his genius lay in selecting for his experimental material strains which differed only in one or two characters, differences immeasurably inferior to those of specific rank. As for de Vries's 'mutations', it has long been recognized, thanks primarily to the work of T. H. Morgan and his colleagues A. H. Sturtevant, C. Bridges and H. J. Muller, that they are not mutations at all, but the results of a rare method of 'sporting' by permanently heterozygous strains technically known as the 'crossing-over of balanced lethals'.

When the author attributes to neo-Darwinians the statement (p 270) that "only the smallest mutations could be favourable and that such favourable mutations were in fact so rare a phenomenon that without natural selection not even a fruit-fly, let alone a man, could have developed", and concludes, "Thus it became the very paucity of variations, the very improbability of their concurrence, that was now made to tell in favour of natural selection", she makes the elementary and very outdated mistake of thinking that mutation is the only supply of variation. It has long been known that recombination of genes is enormously greater as a source of supply of variation than mutation itself, and it produces gradual change.

Dr Himmelfarb has not grasped the fundamental significance of the work of Sir Ronald Fisher, whom she calls "the mathematician". He showed, first, that natural selection of genes within the gene-complex

is a universal phenomenon, which explains why the genes gradually become either dominant or recessive. This is how evolution proceeds. Mendelian genetics itself provides evidence of Darwinian selection. He showed, secondly, that selection is so much more powerful than mutation, that no mutation can have the remotest chance of becoming a normal component of a population if there is the slightest degree of adverse selection exerted against it. He showed, thirdly, that as all organisms are tolerably well adapted to the conditions under which they live in their present environment, the vast majority of mutations are bound to be deleterious to the organisms in the conditions under which they arise, and this proves that any attempt to explain evolution by an appeal to causes which might be supposed to impart favourable qualities or directions to mutations through 'inner feelings', '*élan vital*', 'urges', or the transmission of somatic modifications, is killed stone dead at the start. "Every theory of evolution which assumes, as do all the theories alternative to natural selection, that evolutionary changes can be explained by some hypothetical agency capable of controlling the nature of mutations which occur, is involving a cause which demonstrably would not work even if it were known to exist." The fact that wild species in Nature are highly heterozygous shows that mutant genes, subjected to adverse selection when they first arose, remain as recessives in the gene-pool, and function as a reserve which is drawn on when environmental conditions change, and some of these genes then become dominant by selection in the gene-complex, and established in the population. It can also be shown that selection is exerted in favour of the heterozygous state *per se*.

Results such as those should find a place in any modern appraisal of the position of natural selection at the present stage of knowledge, but Dr Himmelfarb has preferred to say (p 276) that "Posing as a massive deduction from the evidence, it (natural selection) ends up as an ingenious argument from ignorance". The word "ignorance" is a double-edged weapon when it is used by an author without any indication of awareness of the experimental results obtained by such distinguished scientists as E. B. Ford, C. D. Darlington, P. M. Sheppard, A. J. Cain, W. H. Dowdeswell, H. B. D. Kettlewell or C. H. Waddington, to mention only those working in Great Britain.

The intercalation of quotations from Darwin, labouring in his unavoidable ignorance of the principles of Mendelian genetics, to disparage arguments which have since been substantiated by the results of modern experimentation in natural selection is regrettable. When Darwin wrote a hundred years ago that "we are far too ignorant, in almost every case, to be enabled to assert that any part or organ is so unimportant for the welfare of a species that modification in its structure could not have been slowly accumulated by natural selection", he was quite correct, and it was merely tendentious for Dr Himmelfarb to say (p 276) that "three negatives do not normally constitute a positive". When Darwin went on to say that "it would be extremely bold to maintain that no serviceable transitions are possible by which these (electric) organs might have been gradually developed", he was prophetic, as Dr Lissman's researches have since proved. The initial stages in the evolution of flight in birds, colour-vision, or the whale's adaptation for avoiding *caisson*-disease, to mention only a few additional striking

cases have all been shown to be capable of conferring survival value from the inception of the improvement.

The statement (p 277) that "The eye is obviously of no use at all except in its final, complete form" completely ignores the comparative anatomy, embryology and physiology of the lower chordates which show how light-sensitive cells in the epidermis have been brought into place, from the surface of the skin into the neural tube and then into the retinal layer of the eye-cup, and are functional at each stage. Dr Himmelfarb (p 279) accuses Darwin of invoking the perfection of the eye at the same time as he quoted Helmholtz on the inadequacy and imperfection of the eye, but in the 'Origin of Species' (World's Classics edition, p 180), Darwin wrote, "his marvellous yet not absolutely perfect charactera". What Darwin claimed was that natural selection confers improvement, and in the case of the vertebrate eye this is undeniable to anybody familiar with the visual organs in *Amphioxus*.

The statement that "the persistence without change of any form over a long period of time is difficult to explain by natural selection" is particularly unfortunate, because so long ago as 1878 T H Huxley pointed out that natural selection is the only mechanism that can account both for change and for stability, and as recently as 1952 E B Ford supplied the genetic explanation of this by showing that the non continuation of genes and the rarity of mutation produced stability, while the power of recombination of genes can produce endless variability, under the control of natural selection in each case.

How can selection, knowing nothing of the end or final process function which the only test is precisely that end or purpose?" asks Dr Himmelfarb (p 277). The experimental results of investigations on the evolution of industrial melanism in moths show how the selective taking by predators of prey ill adapted to their environment can be seen going on, and the intensity of the selection pressure can be measured with mathematical precision. Mimetic resemblances in butterflies are improved and confer survival value in mathematical relation to the prevalence of distasteful models. The method of capture marking release and recapture enables the predations by thrushes on snails of different colours to be correlated with the seasonal variation of vegetation and the longevity of different genotypic types of moths to be measured in terms of concrete units of time. That is how selection actually operates.

Astonishingly out of date is the statement (p 284) that "the entire discussion of sexual selection is anthropomorphic in its basic conception, for whether the coloration of a bird is judged to be either beautiful or monstrous it is by human standards that the judgment is made. It is now quite clear that the beautiful and monstrous colours in question, to which must be added structures, attitudes and behaviour patterns used in courtship function, as Sir Julian Huxley, N Tinbergen and many others have proved, as stimuli by which a threshold physiological condition in the partner is reached and a release mechanism set in motion. There is no question of any anthropomorphic aesthetic choice.

It is quite correct that many of the examples which Darwin in thought conformed to the principle of sexual selection have since been found to owe their origin to other than epigamic causes, such as warning marks, recognition or threatening defensive characters. But some characters, as those of the male peacock ruff, or argue pheasant, are good examples of the

sexual selection in Darwin's sense, as Sir Julian Huxley showed more than twenty years ago. Yet Dr Himmelfarb concludes (p 300) that "Sexual selection has all the faults of natural selection and more: the suspicious faculty with which it can be made to explain anything and everything, the manipulation of evidence for whatever purposes are convenient, and the invocation of ignorance when all else fails." Here again the historical present tense is used but there is nothing to show that the author does not intend it to apply to the present and that the remarks made represent the actual state of scientific knowledge.

Turning now to another discipline of science we find Dr Himmelfarb stating (p 271) that, "Geology, however, has been notably unforthcoming and instead of being the chief support of Darwin's theory, it is one of its most serious weaknesses." It is difficult to believe that such a phrase could have been written in 1959 for 1959. She goes on to say that "It might have been expected that in those cases where the geological record is more or less complete we would find closely graduated varieties of species existing at the beginning and at the close of the period. Yet even here we do not find such a graduated series." It can only be concluded that she has not held in her hands the series of ammonites from *Laproceras* through *Androgynoceras*, *Amaltheus* to *Pleuroceras* demonstrated by L F Späth nor the series of *Alveolites* demonstrated by D Nichols. As for the series of horses Dr Himmelfarb's information is not more recent than that of T H Huxley in 1870. Actually the fossil series of ancestors of the horse is now so good that George Gaylord Simpson has been able to measure the time required for the conversion of a species into another and the length of life of a species (two million years in horses). T S Westoll had done the same for fish which evolve at different rates. Simpson was also able to show that the geological record in some places is so good that it is now possible to calculate the degree of variability of fossil species and to prove that it is not correlated with their evolution rate. This is further evidence that natural selection not mutation, controls the rate and direction of evolution.

The statement that the geological record is one of the most serious weaknesses of Darwin's theory is ridiculous. Even in his day, the Mesozoic mammals of the Stonesfield Slate had been discovered and that most beautiful of all known fossils, *Archaeopteryx* was known showing such a perfect transition between the reptilian and the avian stages of that line of evolution that it can be regarded as ancestral to all later birds. It also demonstrates the way in which one vertebrate class became converted into another, by piecemeal transformation of bits of the body one by one, a process called mosaic evolution. Other examples of representatives of precursors are *Jamoythus* between the lowest chordates and the fishes, *Ichthyostega* between fishes and amphibians, *Seymouria* between amphibians and reptiles, *Ichthyosaurus* between reptiles and mammals, *Australopithecus* between apes and man. All these and countless others are a striking vindication of Darwin's view.

The sudden appearance in the geological record of representatives of important groups (such as the gastropods or vertebrates) is no fly in the ointment of Darwin's theory, and it receives a logical explanation from the obligatory rarity of tentative initial types and from the principle of candelstick evolution.

tion' of young stages without hard parts and therefore not preserved as fossils until they became adult in their new state. As for the abrupt appearance of fossils in "the lowest fossiliferous strata", the number of fossils discovered in Pre-Cambrian deposits goes on increasing and now includes algae and fungi in which eight amino-acids could still be recognized although they are 1,700,000,000 years old.

Dr Himmelfarb states (p 310) that chemists showed that all the pieces of the 'Piltdown find' revealed the same fluorine content. This was not the case. The earliest estimations by K. P. Oakley and C. R. Hoskins showed fluorine percentages varying from 3.1 to less than 0.1, estimations correct to within a range of ± 0.1 . This proved that all the 'specimens' were not Lower Pleistocene. Subsequent estimations by more refined methods showed that the latest of these were not even Upper Pleistocene. But if Dr Himmelfarb really thinks that the exposure of the Piltdown fraud "leaves the theory (of evolution), after a century of search, without the much desired link", *Proconsul*, *Australopithecus*, *Pithecanthropus* and Neanderthal man are there to bear witness to what Sir Wilfrid Le Gros Clark has demonstrated from them about the so-called 'much desired link'.

If ever the cult of personality should attempt to invade science, it would cease to be science, and if scientists hold Darwin in honour to-day, it is because the evidence, all the evidence, and nothing but the evidence, provided by the observations and experiments of biologists who have undertaken research in this field, has shown that the natural selection of mutant and recombined genes is the mechanism whereby the evolution of plants and animals in Nature has been brought about.

GAVIN DE BEER

THE FAITH OF A REALIST

Blaise Pascal

The Life and Work of a Realist. By Ernest Mortimer. Pp 240+4 plates (London: Methuen and Co., Ltd., 1959) 21s net.

MUCH of Pascal's work, and several books about him, are readily available. What is not so easy to obtain is an assessment of his place in history in keeping with the pedestal upon which his fellow-countrymen are nearly unanimous in placing him. Furthermore, to find an answer to the question as to how much he means to us to-day is assuredly a rewarding task. These things the author has done and the result is a notable achievement. Pascal emerges as a character of gigantic intellectual and spiritual stature, weak of body, indomitable of will, and relentless in his quest for truth.

In the present context, we may perhaps leave aside the well-known facts of his mathematical genius, his contacts with great minds like those of Descartes, Fermat and Desargues, and concentrate upon his theory of knowledge (Chapter 11), which developed from the intense strife going on within him, and which burnt itself out as a consuming fire. Pascal was no mere dreamer, but on the contrary passionately concerned with making things work. His technical skill, if he were alive to-day, would lift him to the summit of electronic computing, and to the highest triumphs of cybernetics and servo mechanisms. In this sense he was a realist,

his faith transcended it, however, as he reached out towards that greater truth only to be found in charity.

It is from some such position as this that we can best approach Mr Mortimer's treatment of Pascal's theory of knowledge, for it is essentially here that the present volume finds much of its *raison d'être*. Here too is Pascal's message for the world to-day.

The central concept is that of *le cœur*. By this Pascal did not envisage something "cardiac rather than cerebral". He uses the phrase to cover a species of synthesis, a type of thought in which analysis gives place to cognition. It seems as if this came out of a state of mind akin to despair, in that, for example, the propositions of Euclid needed acceptance of something "given" before any progress could be made, and thus real knowledge could never be obtained. In this, he was in effect anticipating Gödel's theorem, and the failure of Hilbert to construct a consistent system of mathematics purely mathematically. But for Pascal, truth is not apprehended by reason alone, which can only yield statistical properties.

Mr Mortimer is at pains to point out that Pascal did not draw this inference himself, it is nevertheless the gist of his whole argument. Here indeed is a startling preview of twentieth-century science, quantum theory, operationism and all. Nevertheless, the part to be played by *le cœur* remains, and it stands supreme if we are to 'know' the world around us. But what is it, if it is not rational knowledge? Pascal gives his answer—"Le cœur a ses raisons, que la raison ne connaît point". Metaphysics may be out of fashion at the moment, it looks, however, as if the faith of a great realist may have elevated such a discipline to a position otherwise unheeded.

As people exclaimed in another setting altogether, "We have seen strange things to-day". The author has written a book modest in compass but great in concept. He has brought Blaise Pascal, his tempests stilled at the last, into the centre of contemporary thought.

F. I. G. RAWLINS

ENZYMES—KINETICS AND CHEMISTRY

Behavior of Enzyme Systems

An Analysis of Kinetics and Mechanism. By John M. Rimer. Pp xii+317 (Minneapolis, Minn.: Burgess Publishing Company, 1959) 6.50 dollars.

Proceedings of the International Symposium on Enzyme Chemistry

Tokyo and Kyoto, 1957, organized by the Science Council of Japan under the auspices of the International Union of Biochemistry (IUB Symposium Series, Vol 2). Pp 541 (Tokyo: Maruzen 1958) n.p.

LET Dr Rimer speak for himself. In his foreword addressed to "Timid Souls" he writes, "The foremost purpose of this book, accordingly, is to make it possible for anyone to begin the book knowing substantially nothing, and to finish it an expert for all practical purposes". This is a bold ambition, even when restricted to the field of enzyme kinetics. A major adverse criticism of this book is, in the reviewer's opinion, the almost complete lack of reference to

published experimental work, one has to turn many pages before one can see on the name of an enzyme and there are virtually no numerical data given. Dr Reimer a ideal reader the ignorant but intelligent man but one, nevertheless, longing to learn would find himself bewildered by reality. Putting these criticisms aside this book is a serious piece of scholarship, and provides a useful introduction to the theory of enzyme kinetics.

In contrast to Dr Reimer's solo performance, the Proceedings of the International Symposium on Enzyme Chemistry relating to a conference which took place in Tokyo and Kyoto in October 1957, contains contributions from 228 authors. Apart from four special lectures delivered by Profs Chance (Cytochromes—their Nature and Function in Living Cells), Engelhardt ('Enzymology and Mechanism of Tissues and Cells'), Lynen ("Phosphatkreislauf und Pasteur Effekt") and Tamiya ("The Koji, an Important Source of Enzymes in Japan"), the Proceedings are divided into four sections.

The first section covers the mechanisms of enzymatic group transfer, the second, enzyme systems of hydrogen, oxygen and electron transport, the third, the formation of proteins and enzymes, and the fourth relates to enzymes and industry (interpreted to include pharmacology). Many of the contributions are in effect short reviews (2-10 pages) of specialized topics supplemented with what was in 1957 new experimental material. These articles are in general, of a high standard and are in the main very readable.

The title given to the Conference in no way restricted the range of topics, enzyme chemistry was taken to include any reaction catalysed by enzymes in animals, plants and microorganisms. Papers dealing with the action of thyroxine on isolated animal mitochondria and the role of chlorophyll in photosynthesis occur in the same section.

The majority of contributions are in English, a few in German and even fewer in French. Almost inevitably some of the papers from veterans of international conferences have appeared in substantially the same form before or since.

J. B. CHAPPELL

CHEMISTRY OF PHOSPHORUS

Phosphorus and Its Compounds

By John R. Van Wazer Vol 1 Chemistry Pp xii+974 (Now York Interscience Publishers Inc., London Interscience Publishers Ltd 1958) 208s.

THIS volume must be unique, for it gives in wide scope and considerable detail an account of the structure, the physical and chemical properties and the chemical reactions of phosphorus and all its main classes of compounds both inorganic and organic. It is also outstanding not only for the wide range of the modern scientific information which is so clearly presented, but also for the historical background of this information—each main topic has a historical introduction so that, for example, the discussion of the structure of one class of compound may range from a brief review of the theories of a century ago to a more detailed discussion of the most recent evidence supplied by nuclear magnetic resonance spectra.

The first two chapters deal respectively with the nuclear and atomic structure of the phosphorus atom and with interaction between atoms. The second chapter discusses in detail bond-energies and lengths, dipole moments, polarity of molecules, ionic radii etc. The following chapters discuss in turn various classes of phosphorus compounds. The detailed information available may be assessed from the 380 pages devoted to phosphoric acid and its compounds divided into five chapters on condensed phosphates, orthophosphoric acid, chain phosphates, ring and branched phosphates and amorphous phosphates respectively. This treatment ranges in these five chapters from the physical and chemical properties of phosphato minerals on one flank to those of the nucleic acids on the other. Throughout the book the constant comparison of the properties of the purely inorganic compounds of phosphorus and those of their organic substitution products makes fascinating reading and may well serve both to widen and to readjust the mental balance with which inorganic and organic chemists have hitherto in their different ways assessed the chemistry of phosphorus.

In the preface, the author makes an eloquent plea that the present division of descriptive chemistry into two parts, organic and inorganic, should now be widened to include a third part namely phosphorus chemistry. Many chemists will shrink from this suggestion but it must be admitted that although phosphorus chemistry contains on one hand a number of reactions which can be regarded as normal reactions of inorganic compounds and on the other hand many reactions typical of organic compounds, there lies in the centre a host of reactions and aspects of behaviour which are peculiar to phosphorus. The same statement might possibly be made of the chemistry of other non-metallic elements but the specific chemistry of phosphorus is in its range and nature much greater than that of any other element except carbon. This quality is one of the major factors underlying the vast increase in the academic and technical interest in phosphorus chemistry which has occurred during the past twenty years.

The price of this book may appear high by English standards but the volume contains an immense amount of information liberally illustrated by X-ray structure diagrams, phase rule diagrams etc. and by a wealth of valuable tabulated material. The final three appendices list in turn phosphato minerals (40 pages) giving details of each based largely on Dana's 'System of Mineralogy'; single bond energies and distances with electronegativity differences; and thermodynamic data on the compounds of phosphorus.

The book, however, is emphatically not a mere catalogued compilation of facts. In spite of the size of the book, the author has maintained to the end a critical treatment of the material under discussion and this treatment combined with the author's pleasant and lucid style gives the book a personal flavour which heightens the reader's interest throughout the volume.

The publishers are to be congratulated on the general format and printing of the book and in particular for printing references at the bottom of pages where they can be immediately noted by the reader instead of printing them in a vast huddle at the end of each chapter.

The book will be appreciated by all types of chemist, inorganic, organic, physical and phosphoric.

F. G. MANN

Suggestions to Authors of the Reports of the United States Geological Survey

Fifth edition Pp xu+255 (Washington, D C Government Printing Office, 1958) 1 75 dollars

IN the eighty years that have passed since the foundation of the United States Geological Survey, more than 3,500 volumes of scientific and technical literature and more than 20,000 different maps have been published under its auspices—an output far surpassing that of any other geological institution in the world. Throughout this long history, continuous efforts have been made to promote lucidity, consistency and uniformity in these publications, and the code of practice established by the Survey for its authors, first published in 1909, has found wide spread use outside official circles. The much enlarged fifth edition of this manual outlines the successive literary steps which a geologist-author will normally take from the beginning of an investigation to the final proof-reading of his text, maps and illustrations. It advises on matters of ethics and professional etiquette, enumerates the requirements of a well prepared manuscript, deals at length with questions of typographical style, and gives a great deal of detailed information on the form and content appropriate to reports of various kinds. More than 50 pages are taken up with sensible advice on composition and expression, forming a sort of "A B C of Plain Words" directed specifically at geologists. Not all the suggestions will be acceptable to British readers, who may be somewhat puzzled by the preferred use of 'geologic' and comparable '-ic' endings in a country with a Geological Survey and a Geological Society. But there is no similar guide produced on the eastern side of the Atlantic, and, with appropriate warnings, the work could profitably become prescribed reading for all post-graduate students of geology, as a brake on the present over-production of 'geologese'.

C F DAVIDSON

Causes de la Répartition des Etres Vivants

Paléogéographie, Biogéographie Dynamique. Par Raymond Furon (Evolution des Sciences, No 10) Pp 168 (Paris Masson et Cie, 1958) 1,000 francs

THIS book is well described by its author, in his preface, as "ce petit livre de 'morceaux choisis' n'est donc dans mon esprit qu'une esquisse de ce qui pourrait être un beau livre qui n'existe pas in 'Traité de Biogéographie'", for it touches upon almost every aspect of its subject. Unfortunately the touch is too light to permit the suggestion of solutions to the many problems it describes, and this almost inevitably excites, rather than calms, the doubts that haunt most biogeographers as to whether the chaos of facts with which they are confronted can ever be reduced to final order.

Moreover, so vast a subject can be compressed within the limits of a single short book only by the most careful and balanced selection of information, and of the sources from which this comes, and in this respect also the book leaves more than a little to be desired.

With the author's main conclusions, that the present distribution of organisms chiefly reflects the catastrophic consequences of the Pleistocene glaciations, and that to understand the history of the living world its distribution in the Tertiary must be reconstructed, few biogeographers will disagree. They are likely to agree also that palaeogeography and

palaeontology are the keys to this reconstruction, but they are likely to feel some disappointment that an author so well qualified to comment on these particular aspects of the matter does not give a clearer lead as to how they may be more profitably pressed into service.

The great value of the book is as a source of much useful, and not infrequently unusual, factual information, and as such it can be recommended to all who are interested in the distribution of plants and animals.

RONALD GOOD

Die Banderschnecken

Eine Studie zur Evolution der Tiere. Von Prof. Dr. F. A. Schülder und Dr. Maria Schülder. Schluss: Die Banderschnecken Europas. Pp iv+93-206 (Jena, Gustav Fischer Verlag, 1957) Broschert, 30 30 DM

IN this third and final part of their monumental work on polymorphism in the banded snails (*Cepaea*), Prof. F. A. and Dr. Maria Schülder have tried to give an account of the variation in all parts of the ranges of the four species, and to draw some evolutionary conclusions. The booklet contains much useful information but suggests that such a task requires many more workers. The maps summarizing the data may be adequate for some areas of Germany, but it is well known that the proportions of the different colour and banding forms can vary greatly between adjacent colonies, for some large areas far too few colonies have been investigated for any reliance to be placed on mean frequencies from them as truly representative.

The conclusion reached is that the different forms in the polymorphisms have spread out from centres of special abundance. Lamotte's work is quoted as proving that visual selection by predators can never be of importance. The authors seem unaware of published criticisms of both Lamotte's conclusions, which are certainly invalid for Britain, and of their own inferences from their previous work on *Cepaea*. They combine data from colonies for making inferences about selection, although some at least of these colonies are in disturbed habitats and certainly not in genetical equilibrium with their environments. The composition of such colonies in relation to their habitats need give no indication that selection of any sort is acting, even though in fact it may be very strong. The data are given only to the nearest 10 per cent, and are too inaccurate for re-working.

A J CAIN

The Sea-Horse and Its Relatives

By Gilbert Whitley and Joyce Allan. Pp ix+84 (Melbourne, Georgian House, Pty., Ltd., 1958) 30s net

A PART from a cosy introductory chapter which oozes with unsubstantiated sentimentalities, Whitley and Allan's book will be of value to interested ichthyologists as well as the children for whom it is primarily intended. Besides an account of the lore and legends of sea-horses, there are good descriptions of the structure, behaviour and reproduction of this remarkable fish which Sir J. Arthur Thomson once described as the "most 'kopspeckle' creature of the sea". The systematics of the sea-horse show that about a hundred species have been recorded, and these are distributed over four genera. About half the book is concerned with these and the rest with pipe-fishes, trumpet fishes, flute-mouths, bellows fishes and razor fishes. These, like the sea-horses, are illustrated by some remarkably fine drawings, most of which have been prepared by the authors.

T H HAWKINS

RADIATION OBSERVATIONS WITH SATELLITE 1958₃ OVER AUSTRALIA

By DR. A. J. HERZ, DR. K. W. OGILVIE and J. OLLEY

The F.B.S. Falkiner Nuclear Research Laboratory School of Physics* University of Sydney

AND

R. B. WHITE

Radio Research Board Commonwealth Scientific and Industrial Research Organization
University Grounds, Sydney

In June 1958 the School of Physics of the University of Sydney received a cabled request from the Academy of Sciences of the U.S.S.R. asking for help with the recording of signals from *Sputnik III* (195832). As a result of this request signals from many transits during July and August were recorded with equipment kindly put at our disposal by the Radio Research Board of the Commonwealth Scientific and Industrial Research Organization.

Unfortunately, details of the instrumentation aboard the satellite and of the code used did not reach us until late September 1958, and even now we do not have all the information needed for a complete analysis of the data. We believe, however, that our results are of sufficient interest to be reported at this stage.

Description of Apparatus

It is now well known^{1,2} that among the equipment carried by *Sputnik III* is a scintillation counter. Because of the large size of the crystal (a cylinder of sodium iodide, 40 mm. high and 39 mm. in diameter) the detection efficiency for low-energy photons is high, and fast charged particles give very large pulses, corresponding to the loss of several MeV or more. In particular, the counter responds with high efficiency to bremsstrahlung photons emitted as the result of the absorption of electrons with energies of about 100 keV which collide with the sputnik.

A block diagram of the photon counter and its associated telemetering apparatus is shown in Fig. 1 and Fig. 2 gives the pattern of the signals. The second and third pulses carried the information from the scintillation counter. We do not know what information the first pulse carried.

Fig. 1 is largely self-explanatory. The anode current of the photo multiplier is integrated and fed to a bistable circuit which switches relay A at intervals corresponding to a loss of energy in the crystal of 2×10^6 eV. The current to the seventh dynode similarly controls relay C, which switches at intervals corresponding to an energy loss of 18×10^6 eV. In addition, the last dynode was connected to a scaler which controlled the switching of relay B.

Table 1 POSITIONS OF 195832 DURING OBSERVATIONS

| Epoch | Time (UT) | Altitude (km.) | Latitude | Longitude |
|---------|-----------|----------------|----------|-----------|
| July 10 | 06500 | 2050 | 1 605 | 20° S |
| July 19 | 07431 | 2059 | 1 753 | 4 9° S |
| July 23 | 81550 | 1920 | 1 703 | 23° S |
| July 23 | 81359 | 1092 | 1 507 | 27° S |
| July 30 | 74514 | 1763 | 1 794 | 20° S |
| July 30 | 74501 | 1758 | 1 800 | 22° S |
| Aug 4 | 70550 | 1656 | 1 782 | 27° S |
| Aug 4 | 70764 | 1659 | 1 750 | 34° S |

At the time our observations were made the scaling circuit had ceased to operate so that relay B remained in a fixed position throughout. So channel 2 (the second pulse) transmitted information about the position of the anode-current relay A, and channel 3 about the seventh-dynode-current relay C. On most of our records the marker and the first-channel pulse are missing as part of the modulating equipment was operating only intermittently, but the data given in this report are all taken from records in which all the pulses are present.

Positions of the Satellite during Observations

The positions of 195832 used by us were calculated with the aid of the elements of the orbit published by the Smithsonian Institution and with an orbital period found from a least squares fit to the transits observed at Sydney.

The results of these calculations are given in Table 1 and displayed in Fig. 3.

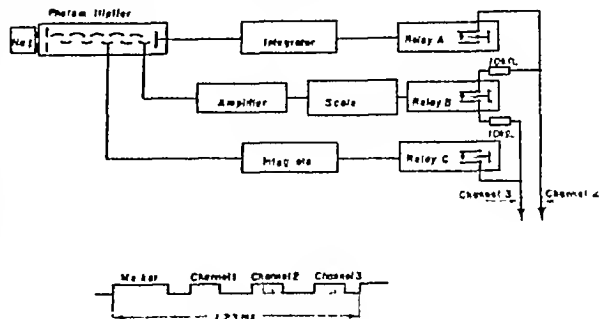

Fig. 1 (above) and 2 (below)

* Also supported by the Nuclear Research Foundation within the University of Sydney

Fig 3

Results and Conclusions

The rates of energy loss in the crystal during our five recording periods are plotted as function of time (τ) in Fig 4. Combining these with the positions of the satellite (Fig 3 and Table 1) we find a minimum of radiation intensity at a geographic latitude of about 35° S. The intensity appears to increase by an order of magnitude when the latitude changes by approximately ten degrees on either side of this minimum. Similar observations over Australia, made with satellite 1958 α (*Explorer IV*), have been reported by Van Allen *et al*², who suggested that these minima correspond to outward-projecting 'horns' in the contours of constant radiation intensity. The minima can presumably be interpreted as the gap between the inner and outer radiation belts which have recently been discovered by means of the Russian artificial planet⁴ and by Van Allen and co-workers using the American lunar probes.

Fig 4

Our data also suggest a time variation in the radiation intensity. The mean intensity during the first part of the transit of July 19 (see Fig 4) is about five times the mean for August 4 although the satellite moved through almost exactly the same region in the two cases. We do not know whether the distribution of absorbing matter around the scintillator is such that tumbling of the sputnik could cause such large fluctuations, but, in any event, we do not believe that the fluctuations are so caused since our observations of the signal strength suggest a tumbling period not greater than about 40 sec — much less than our intervals of observation.

We tentatively conclude that the intensity of radiation in the region observed may show very considerable variations with time. This may be of particular significance as the region in question straddles the gap between the two radiation belts.

Our remaining conclusions concern the ratio of the switching rates of relays A and C. It appears to us that the telemetering equipment was not designed to handle the high switching rates, especially of relay A, which corresponds to the intensities of radiation encountered by the satellite. The switching rate of relay A almost always overloaded channel 2 during our periods of observation. We were, however, able to obtain adequate data on the rates of loss of energy through channel 3—these are the ones plotted in Fig 4.

When a large charge passes through the later stages of a photomultiplier, its anode current response becomes non-linear, and for extremely large flashes of light the current from the dynodes also becomes a non-linear function of the light input. The ratio of the switching rates of relays A and C therefore depends on the average magnitude of the light flashes at low counting rates, and on the average light output from the scintillator at counting rates so high that the interval between the individual events in the crystal is less than the decay time of the light pulses (about 5 μ sec in sodium iodide). According to Vernov *et al*¹ the ratio of the switching rates of relays A and C is 9:1 if the photomultiplier operates in the linear region of its response curve, it will be less if an appreciable number of the pulses is caused by particles which lose large amounts of energy in the crystal, and it will also be less if the number of photons detected in unit time is extremely large.

It was therefore of interest to try to find values for the switching rate of relay A, and we were able to do this as we explain in detail below. The results show that the ratio of the switching rates was of the order of 4:1, with fluctuations in the range 3.8:1 to 6:1. Individual results are shown in Table 2, they suggest that the ratio decreased with time. As we have no information about the response curves of the apparatus we cannot draw conclusions about the nature of the radiation from this.

Table 2 THE RATIO p_C/p_A

| Epoch | Time (τ) | p_C/p_A |
|--------------------------------|-----------------|---------------|
| July 19 86800 to July 19 87431 | 2050 to 2050 | 5.0 \pm 0.3 |
| July 23 81250 to July 23 81789 | 1929 to 1932 | 4.4 \pm 0.1 |
| July 30 74514 to July 30 74861 | 1753 to 1758 | 3.0 \pm 0.2 |
| Aug 4 70556 to Aug 4 70764 | 1656 to 1659 | 3.0 \pm 0.2 |

Recording Method

The receiving aerials were two horizontal dipoles placed at right angles to each other. Each dipole

Fig 5

fed a communications receiver and the rectified signals from the second detectors were further amplified by two separate d.c. amplifiers. The two outputs were then summed by a resistive mixing network and the resultant was applied to the deflecting plates of a cathode ray tube. The spot was photographed on 35 mm film moving perpendicular to the direction of deflection at a speed of 0.6 in./sec (1.52 cm/sec).

Characteristics of the Signal

A sample of one of our records, showing complete pulse trains with marker pulses and first pulses is given in Fig 5. The pulse-lengths were measured with the aid of a travelling microscope. A sample of a pulse length distribution (for the transit of July 23) is shown in Fig 6.

The various combinations of positions of relays A, B and C lead to pulses of nominal lengths 50, 100 and 150 μ sec, which we designated short, 'medium' and 'long'. As the position of relay B was fixed the second-channel pulses were either long or short, depending on the position of relay A only, and the channel 3 pulses were of either short or medium length. It is clear from Fig 6 that in both channels there occurred a number of intermediate length pulses—these were caused by the switching of a relay while a pulse is being transmitted.

With the aid of time markers recorded on the film we were able to measure the pulse lengths. The results are given in Table 3.

Table 3. LENGTHS OF PULSES AND PULSE TRAINS

| | Nominal value (μ sec) | Mean used (μ sec) |
|------------------------------|-------------------------------|---------------------------|
| Short pulses | 50 | 60 ± 9 |
| Medium pulses | 100 | 115 ± 8 |
| Long pulses | 150 | 161 ± 10 |
| Pulse train including marker | 1,250 | $1,210 \pm 20$ |

Vernor et al. (ref. 1)

Analysis of the Records

In the system of telemetering used the positions of the relays are sampled at regular intervals of 1.23 sec (the cycle length). A change in the length of the appropriate pulse occurs whenever the number of switchings during the preceding cycle was odd, no change is found when the number of switchings was even. If a relay is switched during transmission of the pulse the length of which it controls, a pulse of intermediate length occurs.

If the relay is switched at intervals which are large compared with the length of the sampling cycle every switching results in a change of pulse length. Common sense suggests that the converse is also true—that changes in pulse length at intervals large compared with the cycle length denote an equal

number of switchings, each of which occurred during the cycle immediately preceding the change. Although not strictly true as we shall see below this turns out to be almost always correct.

For more detailed analysis we plot (Fig 7) the interval between pulse length changes as a function of the interval between switchings of the relay. It is clear that if the interval between switchings were really constant and if there were no additional information we should not be able to deduce a unique value of the switching frequency from the observations of changes in pulse-length. Fortunately, however the intervals fluctuate and we have other data as well.

The published information shows that if the photomultiplier is working in the linear region of its anode current characteristic the ratio between the switching rates of relays A and C is 9:1. Over loading cannot increase this ratio, so that we accept only those pairs of switching rates which have ratios of 9:1 or less. Secondly as Fig 7 shows the lengths of the intervals between changes are very sensitive to changes in the switching rate when there is more

Fig 7

Fig 8 July 30, 1959 1753-58 GMT

Fig 9 July 10, 1959 2050-59 GMT

than one switching per cycle. In the presence of fluctuations it is thus quite unlikely for high switching rates to give rise to long successions of pulses of equal size, that is, to consistently long intervals between changes in pulse-length. We conclude that if the intervals between pulse-length changes are consistently longer than the sampling cycle, the frequency of the changes is equal to the switching frequency of the relay concerned. During most of our observation time the less-sensitive channel 3 operated in this way so that we could deduce the radiation intensity directly from the frequency of pulse-length changes in it.

With one exception, at 1758 UT on July 30 (see Fig 4), the intervals between the switchings of relay A in channel 2 were always less than the length of the sampling cycle. The intervals between pulse-length changes thus rarely exceeded two cycles, and

we could not obtain information about the rate of switching from the average magnitude of these intervals alone. However, for the reasons discussed earlier we felt it worth while to try to estimate the switching frequency of relay A.

The possible values of the interval p between switchings can be obtained from Fig 7, and the smaller values of the intervals p_A (between the switchings of relay A) can usually be eliminated because of the requirements that the ratio p_C/p_A cannot be greater than 9. In most cases we were still left with several possible values of p_A from which a choice had to be made using the patterns of pulse sizes in both channels.

Two additional pieces of information helped us here. First, the ratio of the switching rates is not likely to show violent discontinuous changes. Secondly, in spite of fluctuations, there will be a brief series of equal-width pulses (no changes) whenever the number of switchings per cycle is nearly equal to an even integer ($p = 1/n$ cycle lengths where n is even). Whenever there is an odd number of switchings per cycle there will be a series of pulse-length changes every cycle. This effect, though not very pronounced, is clearly observable.

In our analysis we used a graphical method of display, of which we show examples in Figs 8 and 9. Along the horizontal axis we plot the times of occurrence of changes in pulse-length, while the ordinate gives for every change the time elapsed since the immediately preceding one.

We also indicate on the diagrams our estimated values of p_A and p_C and of the ratio p_C/p_A . The intervals p are measured in units of one cycle-length.

Fig 8 shows the record corresponding to our lowest detected radiation intensity—the only case when we found p_A to be undoubtedly greater than unity. It can be seen clearly that p_C/p_A is approximately equal to 3.8—much less than the nominal value 9.

Fig 9 is a display of data from an observation period during which the radiation intensity was high and changing rapidly. According to our estimates, p_A varied from approximately $1/2$ cycle to $1/10$ cycle during the time covered by the diagram, and the record shows particularly clearly the peaks in the plot associated with even integral values of $1/p_A$, and the runs of pulse-length changes every cycle which occur when $1/p_A$ is odd.

We should like to thank Prof H Messel for the excellent laboratory facilities made available to us, and Dr G H Munro, the officer in charge of the Sydney Section of the Radio Research Board, for making possible the recording of the sputnik transmissions. To Academician L I Sodov we are grateful for an informative discussion during his recent visit to Australia, and for the reprints he presented to us. We are much indebted to Miss Xenie Federoff for the careful and conscientious way in which she

carried out the tedious work of reading the records. One of us (J O) would like to thank the Commonwealth Scientific and Industrial Research Organization for the award of a studentship.

ROBERT HOOKE AND BOYLE'S AIR PUMP

By DR. H D TURNER

University of Sheffield

IT is just three hundred years since Robert Hooke built Boyle's air pump. This event has been described by Gunther¹ as "the most important research ever brought to a successful issue in Oxford", and it is perhaps appropriate to mark the tercentenary by examining the truth of this statement and, incidentally by somewhat belatedly giving Hooke the acknowledgment which is his due for his share in the enterprise.

Robert Hooke who was born on July 18 1635 at Freshwater in the Isle of Wight, was the son of the local curate. He was a sickly child and never robust, but he gave early evidence of that mechanical aptitude which led to his being described as "certainly the greatest mechanick this day in the world".² After the death of his father, Hooke went, at the age of thirteen, to Westminster School, and in 1653 he went to Christ Church, Oxford as a chorister, being admitted to the degree of Master of Arts in 1663. During the latter part of his stay in Oxford Hooke was employed as a laboratory assistant by Boyle, and in 1659 he built the air pump shown in Fig 1.

At this time Hooke was very much interested in the mechanical properties of the air, and very dissatisfied with the behaviour of the air pump then available, that due to Otto von Guericke. In 1660 Boyle wrote his famous treatise on the "Spring of the Air".³ In this book, which was dedicated to his nephew Lord Dungarvan, he says:

"As few inventions happen to be at first so complete, as not to be either blemished with some deficiencies needful to be remedied or otherwise capable of improvement. so when the Engine we have comes to be more attentively considered there will appear two very considerable things to be desired in it.

"For first the Wind Pump (as somebody not im- properly calls it) is so contriv'd that to evacuate the Vessel there is required the continual labour of two strong men for divers hours. And next, (which is an imperfection of much greater moment) the Receiver or Glass to be employ'd, consisting of one entire and uninterrupted Globe and Neck of Glass; the whole Engine is so made that things cannot be convey'd into it whereon to try Experiments. So that there seems but little (if anything) more to be expected from it than those very few Phenomena that have been already observed by the Author and recorded by SCHIOTTUS."

Boyle then goes on to say that he asked Hooke to contrive a more effective air pump

"Wherefore to remedy those Inconveniencies I put both Mr G(RATORIN) and R HOOK (who hath also the honour to be known to your Lordship and was with me when I had these things under consideration) to contrive some Air Pump that might not like the other, need to be kept under water (which on divers occasions is convenient) and might be more easily managed. And after an unsuccessful tryal or two of wavs propos'd by others, the last named Person fitted me with a Pump upon to be

Fig 1. Boyle's air pump built for him by Robert Hooke in 1659. This was a notable advance on O. v. Guericke's pump since the evacuated enclosure was easily accessible and the receiver system enabled one man to operate the pump without undue effort. Hooke later built a double-acting pump which was even more effective and flexible in operation.

described. And thus the first imperfection of the German Engine, was in good measure, though not perfectly remedied."

The cylinder of the pump was bored in London, but the rest of the machine was constructed by Hooke in Oxford. The technical difficulties were evidently enormous. Boyle goes on to say:

"Your Lordship will, perhaps, think that I have been unnecessarily prolix in this first part of my Discourse. But if you had seen how many unexpected difficulties we found to keep out the external Air, even for a little while, when some considerable part of the internal had been suck'd out, you would peradventure allow that I might have set down more circumstances than I have, without setting down any, whose knowledge, he that shall try the experiment, may not have need of."

Once an efficient air pump was available, there were many experiments which could be performed. One of the first investigations carried out by Boyle was into the relationship between the pressure and volume of a gas.

This led to the enunciation of 'Boyle's Law' or 'Boyle and Mariotte's Law' after its confirmation by Mariotte in 1676. Although Boyle does not explicitly name Hooke as his assistant and collaborator in this work, Gunther¹ believes that he was. At this time Boyle was suffering from weakness of eyesight, and he also complained of a lack of skill in geometry which made him "both unwilling and unfit to engage in any Study where the conversing with Mathematical Schemes is necessary." The suggestion is that Hooke, a skilled experimenter and a very able geometer, was, in fact, mainly responsible for the enunciation and proof of Boyle's Law.

Hooke himself carried out many experiments with the air pump. In 1662, having been released by Boyle, he went to London as curator of experiments to the newly formed Royal Society. In this capacity he had to demonstrate different experiments two or three times a week for the delectation of the Fellows, and in many of these he used either the air pump, or the condensing engine, a compressor which he built in 1662-23. For example, in April 1663 we find Hooke experimenting with water freed of air which, according to Huygens, did not subside in a Torricellian tube, and later, air was removed from above and within water containing various fish to see which would die soonest.

This work with fish undoubtedly stimulated an interest in the general problems of respiration and combustion, and we may suspect that this was not unconnected with the interest that the Royal Society was then taking in the problems of diving. In 1664 we find Hooke giving an account of an experiment with two birds, one of which was kept in compressed air and the other in air at ordinary atmospheric pressure. He also constructed a container, large enough to hold a man, which could be partially evacuated by the air pump. Hooke experimented on himself in this device, thus anticipating modern investigations into human behaviour under reduced atmospheric pressure. He tells us that when a quarter of the initial air had been extracted he was able to endure for "somewhat above a quarter of an hour without any other inconvenience than feeling some pain in his ears, and finding himself deaf." During this experiment Hooke took a lighted candle into the container and discovered that it was extinguished long before he experienced discomfort. Other experiments carried out at this time involved

the development of an air gun, the measurement of air pressure and experiments with diving bells, but the most important aspect of this period of experimentation is undoubtedly the insight which the use of the air pump gave Hooke into the mechanism of combustion and respiration. The culmination of this work was, in fact, the publication by Hooke in 1664 in "Micrographia", of his theory of combustion².

In 1680 Denis Papin, who invented the 'digester' (the prototype of the modern pressure cooker), joined Hooke as his assistant. He later developed a 'steam pump' in which water was forced, by expanding steam, into a container from which it was ejected, under pressure, on to the paddles of a water-wheel, and this has been regarded by some French authors as the first steam engine.

Papin's claims in this direction, however, must, one feels, rest on his contributions to the development of the atmospheric engine. For some time on the Continent there had been interest in the possibility of producing power by using the pressure of the atmosphere to force a piston along an evacuated cylinder. Various ways of producing the vacuum had been tried. Guericke³ had described an experiment in which a cylinder had been evacuated by using his air pump. Huygens⁴ had blown the air out of a cylinder by the detonation of a small charge of gunpowder, and Papin⁵ had used the apparatus shown in Fig. 2 to produce a vacuum by the condensation of steam. Like many other members of the Royal Society at this time, Papin was aware of the enormous problem of clearing flooded mines.

Fig. 2 Papin's cylinder and piston device, 1680 (Crown copyright). From an exhibit in the Science Museum, South Kensington. Steam generated by heat from the fire allowed the piston to rise to the top of the cylinder, where it was locked in position by the movable rod. The device was removed from the fire, the steam condensed by pouring cold water on the cylinder, and on releasing the piston it was forced down by air pressure, thus raising the counterbalanced weight.

which were frequently distant from sources of water power. In 1686 he proposed a scheme for the transmission of power over considerable distances. A water wheel was to drive two large air pumps, the air contained in pipes attached to these would be alternately rarefied and compressed at the mine the suction and pressure would alternately lift water from the mine and then expel it. In 1688 he proposed a modification of this in which a conveying pipe was to be evacuated by a water-driven air pump, at the mine the conveyance pipe was connected by branched pipes and valves to two vertical cylinders fitted with pistons these were connected by ropes to an axle carrying a winding wheel around which was wound another rope carrying buckets at each end. As each cylinder was evacuated in turn, external air pressure would force its piston down, thus turning the wheel first clockwise then anticlockwise and hence the buckets would be alternately raised and lowered.

Hooke's influence on these projects and his contribution to the ultimate development of the atmospheric engine is now, unfortunately, undocumented. Our only evidence of his interest and suggestions comes from references made by Dr Robison⁶ of Edinburgh. Among the latter's papers after his death was found a "List of Dr Hooke's Inventions" which contained the following sparse note, "1678 proposed a Steam Engine on Newcomen's principle", which implies that he had anticipated later developments in this field. Robison also claimed to have seen among the Royal Society's collection of Hooke's papers memoranda of a letter addressed to Thomas Newcomen, of Dartmouth these memoranda were however not in the possession of the Royal Society in 1880. According to Robison, Newcomen and John Cawley, a glazier, were anxious to make an engine on the lines suggested by Papin in 1688. Newcomen was in touch with Hooke and wrote to ask his advice. Hooke had already criticized both Papin's projects on the ground that the great compressibility of the air in the conveyance pipe would result in negligible effects at the mine unless the water-driven pumps had inordinately long strokes. In replying to Newcomen Hooke said "Could he [Papin] make a speedy vacuum under your second cylinder your work is done".

This suggestion was taken up by Newcomen and Cawley, who probably knew of Papin's piston and cylinder experiment and who certainly knew of the methods employed by Savery in operating his pumping machine "The Miner's Friend". According to Stuart¹⁰, "They therefore made the experiment of introducing steam under a piston moving in a cylinder and formed a vacuum by condensing the steam by an affusion of cold water on the outside of the steam vessel and the weight of the atmosphere pressed the piston to the bottom of the cylinder".

This method of producing a vacuum by the condensation of steam had been patented by Savery. An agreement was therefore entered into between Savery, Newcomen and Cawley and they were all associated in the grant of a monopoly for the atmospheric engine which was made in 1705.

The construction by Hooke of the first efficient air pump undoubtedly exercised a profound effect on the development of science and technology in the second half of the seventeenth century. Not only did the use of this machine lead to an understanding of the physical properties of gases and to a theory of combustion which is strikingly similar to the modern theory, but also it focused attention on the properties of systems of pistons and cylinders and the pressure of the atmosphere. This was certainly important in providing the climate of opinion in which the atmospheric engine could develop and as we have seen, there is reason to believe that in this development too, Hooke played a decisive part.

CANCER AND THE RESPIRATORY GRANA

By PROF CARL C LINDEGREN

Biological Research Laboratory Southern Illinois University Carbondale, Illinois

WARBURG'S¹ theory of the origin of cancer proposes that tissue specificity can be achieved only by the synthesis of substances which make tissues specifically different through oxidative metabolism in the grana which carry the oxidative enzymes. Accordingly, the loss of tissue specificity begins with the loss of oxidative capacity through injury to the grana. Since a source of energy is essential the cell can only survive the loss of its oxidative apparatus if the oxidative apparatus is replaced by the adaptive development of the fermentative apparatus. The loss of oxidative capacity is not reflected by an immediate loss of tissue specificity but when the

injured cell divides and the daughter cells begin to grow, they do not achieve tissue specificity because the energy produced by fermentative metabolism cannot produce it. Warburg has focused attention on the oxidative grana of the cell, mutation the carcinogenic poisons, viruses, mechanical irritations, anaerobiosis, radiation and all other indirect causes of cancer and influences similar to hormonal control are assumed to affect the autonomous grana and thus to affect tissue specificity only through their action on the grana. Warburg has unified all ideas concerning the origin of cancer into a single concept involving material organelles capable of

observation and metabolic investigation, thus making it possible to bring the phenomenon under test and observation. In this respect, the theory is (as Warburg says) the only explanation of the origin of cancer cells which can be "metabolically specified". The essential aspects of the theory are summarized by Warburg: "Cancer cells originate from normal body cells in two phases. The first phase is the irreversible injuring of respiration... there is only one common cause into which all other causes of cancer merge, the irreversible injuring of respiration."

"The irreversible injuring of respiration is followed, as the second phase of cancer formation, by a long struggle for existence by the injured cells to maintain their structure, in which a part of the cells perish from lack of energy, while another part succeeds in replacing the irretrievably lost respiration energy by fermentation energy. Because of the morphological inferiority of fermentation energy, the highly-differentiated body cells are converted by this into undifferentiated cells that grow wildly—the cancer cells."

Although Warburg's theory concerns the problem of dedifferentiation, it does not explain how the cell became differentiated. It has been pointed out by others that the cancer cell is not dedifferentiated back to the embryonic level but always retains some characteristics which make it identifiable with regard to origin. Thus the loss of tissue specificity does not involve complete but only partial 'dedifferentiation'.

Differentiation is also achieved in organisms in which defined cells do not exist, since the Ascomycetes, which are coenocytial, are highly differentiated. Even though the nuclei flow freely through the false septa throughout the thallus, differentiation into mycelium, conidiophore and conidium is achieved in circumstances so fluid that no specific cell can be identified. This differentiation requires, like all other differentiation, the activity of many genes, since many nonconidial forms of *Neurospora* are known each of which is the phenotype of a different recessive allele. It may be inferred that differentiation is effected differently in cellular and noncellular organisms.

Although we all speak freely about 'yeast cells', it should be pointed out that phylogenetically yeasts are also noncellular organisms which graduate from mycelial or coenocytial forms to budding varieties all of which seem to be relatively closely related. The so-called yeast 'cell' and its bud is simply a coenocytial form which partitions single nucleate buds with a surrounding wall, much as *Neurospora* forms microconidia. Although this might seem like splitting hairs, it is a vital point in cell theory. The 'cell' that Warburg means is the cell of a multicellular organism.

A dominant scientific theory remains the dominant theory until it is replaced by a subsequent theory, because scientific effort can only be carried out under the aegis of a theory which restricts the activities and directs the efforts toward the examination of fundamental principles. Warburg's theory is to-day the dominant theory, by unifying the concept Warburg has made all other ideas concerning the origin of cancer subsidiary to his. In the absence of an alternative theory, one does not reject a theory by indicating extreme dissatisfaction with it (for example, Weinhouse¹), since no scientific activity is conceivable without a guiding theory. The most adverse criticism notwithstanding implies acceptance *ipso facto*.

The first step in criticism of the theory is the specification of the assumptions upon which it is

based. Warburg has assumed (1) that the ascitic tumour cell is a typical cancer cell, (2) that differentiation and tissue specificity in cellular organisms are achieved by oxidative metabolism of the grana (the respiratory grana have functions other than tissue differentiation, since they play an active part in the metabolism of yeasts), (3) that the grana are autonomous, and, therefore, (4) that the oxidative apparatus cannot be synthesized *de novo* (recent, unpublished, experiments in this laboratory have revealed that respiratory-deficient yeast cells, which never recover respiratory capacity spontaneously, can in certain unique conditions become respiratory-sufficient by exposure to yeast homogenates), (5) that cells which have lost oxidative capacity may obtain their energy by fermentation, (6) that division of these fermentative cells leads to the loss of tissue specificity, since they cannot obtain the oxidative energy essential to differentiation, (7) that such cells can neither fit into the tissue to perform the tissue function nor be restricted by the agents which restrict the differentiated cell and, therefore, form tumours, (8) that oxidative capacity can be injured (a) by oxidation of narcotics on the grana, (b) by direct action of specific poisons, (c) by anaerobiosis, (d) by radiation and (e) by various other items which are carcinogenetic. Research aimed at understanding cancer (as distinguished from applied research aimed at methods relieving the symptoms, study of surgical procedures, discovery of drugs for destroying cancer by large scale canvases, etc.) requires an investigation of the validity of these assumptions and a reformulation of theory depending on the results of such investigations.

Warburg's theory presupposes that the aerobic apparatus is a recent phylogenetical achievement. It is clearly a late, almost certainly the last, great advance made by the free cell in evolution, since it could only occur after photosynthesis had made oxygen available. Its recent integration into the cell probably accounts both for its autonomy and its vulnerability. (The respiratory grana and the chloroplasts are both autonomous structures which were obviously integrated into the cell recently, presumably before multicellular organisms evolved. It is reasonable to suppose that the chloroplast was the original symbiont added to the cell—or to the coenocyte—and that it later evolved into the respiratory granum with the advent of oxygen.) Since the autonomous aerobic apparatus seems universal, it may have been perfected when cells existed only as free cells, before the advent of the differentiated multicellular Metaphyta and Metazoa. The adaptive enzymic fermentation in yeasts, which is normally achieved by oxidative metabolism, may also be achieved by fermentative metabolism, albeit more slowly and less efficiently. Warburg might say that enzymic adaptation in single celled microorganisms is a 'cytoplasmic' activity and thus different from 'true' tissue specificity in multicellular organisms. On this theory, true tissue specificity may have appeared after the advent of oxygen.

A striking difference between yeast cells and mammalian cells lies in their means of obtaining energy. Yeast cells, unlike mammalian cells, have two separate fully functional systems for supplying adenosine triphosphate—an oxidative and a fermentative system. Yeasts can grow oxidatively or fermentatively without previous preparation, unlike the mammalian cells which can adjust themselves to a fermentative mode of existence only (according to Warburg).

by slow degrees. In this sense, mammalian cells are almost obligate aerobes. No obligately aerobic yeasts are known since the anaerobic metabolism in yeasts is always available as a source of energy. In some yeasts (in which the aerobic pathway has been lost) the anaerobic pathway is the only source of adenosine triphosphate. Yeasts are markedly different from the filamentous fungi, like *Neurospora*, in which it is difficult to demonstrate the fermentative pathway and which resemble mammalian tissue in growing only poorly, if at all under anaerobic conditions.

This discussion suggests that the yeast cell can provide a fruitful research object for study of the sensitivity of the respiratory apparatus and thus a guide in the evaluation of carcinogens. Many kinds of poisons have been tested with this view in mind. An interesting poison which was introduced to us by Dr Seymour Hutner is propamidine isethionate. It is widely used in the tropics as a specific for kala azar. It is thus important to know whether or not it may be carcinogenic. Our present indications are that it destroys the respiratory apparatus too completely, too rapidly and too specifically to be a carcinogen—if the data from yeast cells are transferable to humans. When yeast cells are smeared on the surface of an agar plate and a paper filter pad saturated with a solution of 1760 p.p.m. of propamidine isethionate is placed in the middle of the plate a zone (several cm wide) appears around the disk in which the yeast cells grow abundantly but in which none of the cells is capable of utilizing oxygen. Since the original cultures were respiratory sufficient, it is inferred that propamidine isethionate has destroyed the respiratory apparatus. The living cells in the zone around the disk have been irreversibly transformed into obligate anaerobes. This is demonstrated by inoculating the cells from the zone into a peptone yeast-extract broth containing sodium acetate as the major source of carbon. The medium contains phenol red as an indicator, and if a single cell with an intact respiratory apparatus is introduced into this medium it will grow and the medium will turn deep red due to the increase in pH.² Although cells from the area surrounding the disk grow well in glucose broth transfers to the acetate broth never produce an alkaline reaction proving that all the cells have lost their ability to respire acetate and hence are respiratory-deficient. The conclusion that propamidine isethionate has destroyed the respiratory apparatus irreversibly seems irrefutable. It also appears to have achieved this end with relatively little harm to the cell otherwise.

This experiment is simplified by using a yeast which is incapable of synthesizing adenine since strains of this kind with an intact respiratory apparatus are pink while the respiratory deficient strains are white.³ When this experiment is performed with a pink yeast, the yeast which appears in the zone surrounding the disk is white although it remains adenine-dependent. White cells from such a plate always fail to grow after transfer to the acetate broth, justifying the inference that all the cells have lost their respiratory apparatus since a single cell with an intact respiratory apparatus would be able to utilize the acetate and grow in the acetate broth. A poison of this type which acts abruptly and completely on the respiratory apparatus might be assumed on Warburg's theory not to be carcinogenic because it acts so quickly and completely that the mammalian cells (which do not have a fully formed anaerobic pathway available and waiting) would not be able to adapt

themselves to anaerobic growth. The phenomenon demonstrates the extreme sensitivity of the respiratory apparatus to a poison which has little or no effect on the survival of the cell.

Warburg's theory assumes that low oxygen tension can lead to crippling of the autonomous grana and thus to cancer. Warburg's inference that respiratory deficiency could be induced by anaerobiosis was confirmed by Hino and Lindegren⁴ using yeast (Respiratory-deficient yeasts induced by anaerobiosis or by a variety of other treatments are completely capable of maintaining their structural integrity permanently from generation to generation although all the cell's energy is supplied only by fermentation. Warburg quoting Pasteur stated that not even yeast which is one of the lowest forms of life can maintain its structure permanently by fermentation alone; it degenerates to bizarre forms.⁵ This view concerning the stability of yeast grown exclusively anaerobically is in error but this fact has no bearing on the validity of Warburg's theory of the origin of cancer since it neither supports nor invalidates any of the assumptions upon which the theory is based.) Both Sarachek⁶ and Harris⁷ failed to confirm the induction of respiratory deficiency in yeast by anaerobiosis. In three haploid cultures Hino and Lindegren found that the frequencies of respiratory-deficiency under aerobiosis were, respectively 1.7, 3.8 and 3.3 per cent, while the same cultures grown anaerobically produced respectively, 14.9, 8.6 and 8.0 per cent. Two diploid cultures under aerobic conditions produced respectively, 0.8 and 0.0 per cent respiratory-deficiency and 1.9 and 0.2 per cent under anaerobic conditions. In one tetraploid culture the frequency of respiratory deficiency rose from 0.0 under aerobiosis to 0.3 per cent under anaerobiosis. It is clear that the haploid state provides the clearest demonstration of the effects of anaerobiosis on respiratory-deficiency, and it is not surprising that neither Sarachek nor Harris detected this effect since they did not use haploid cultures. Anaerobiosis (unlike propamidine isethionate) induces only a low frequency of respiratory deficiency; the effect of propamidine isethionate is total. Anaerobiosis produces relatively minor damages which might be progressive. If repeated since only a few of the grana are affected in most cells and only rarely are all destroyed. Anaerobiosis is inferred to be an effective carcinogen since it only reduces partially the energy available from aerobiosis and thus enables the cell to survive long enough to adapt the dormant fermentative system.

Recent work in this laboratory⁸ has provided an example of another kind of induction of respiratory deficiency in yeast. Caffeine induces respiratory deficiency in yeast cells sensitive to caffeine with much higher frequency than in cells resistant to caffeine. Growth in caffeine is only achieved by an adaptive process, presumably an enzyme adaptation. Both resistant and sensitive yeast cells pass through the adaptation but the adaptation of sensitive cells is characterized by the simultaneous induction of an extremely large number of respiratory-deficient cells. Although one may assume that the total induction of respiratory deficiency by propamidine isethionate is due to the direct action on the grana the induction of respiratory deficiency which occurs when caffeine sensitive cells become adapted to caffeine may be due to injury of grana, not by direct action of caffeine upon the grana but through the metabolic stress imposed by oxidative

The metabolic stress of adaptation can be observed cytologically. Several years ago when interest in the laboratory centred on adaptation of yeast to galactose, yeast cells were critically observed during adaptation. In the early stage of adaptation most cells were not budded and did not stain with methylene blue (Non-stainability is the standard criterion for viability). Just before adaptation was achieved (as indicated (1) by the absence of budding, (2) by the failure to accumulate glycogen, (3) by slow utilization of galactose) nearly all cells became stainable with methylene blue. In other circumstances this would indicate that the cells were non-viable. Shortly thereafter, however, at least 80 per cent of the cells produced buds, lost their stainability with methylene blue, and vigorous fermentation of galactose occurred. This is interpreted to mean that the stress of adaptation had exhausted most of the reducing reserves of the yeast cell, permitting it to stain with methylene blue, but that this deficiency was made up as soon as sufficient galactose became available.

An important use of Warburg's theory is for predicting the possibility that an agent is a carcinogen from its action on the respiratory grana. On this theory, propamidine isethionate is predicted not to be carcinogenic whereas anaerobiosis and caffeine are. The dye janus green, which acts specifically to stain the respiratory grana and which is singularly effective in preventing sporulation in yeasts, is predicted to be non-carcinogenic. Incidentally, the sporulative process in *Saccharomyces* is an especially useful point for testing the effectiveness of various toxic agents on the respiratory grana, since it is a highly specific kind of differentiation which is achieved only aerobically. The view that viruses may cause cancer can also be deduced directly from Warburg's theory. Warburg inferred that a great variety of metabolic disturbances could inactivate the respiratory apparatus, and experimental evidence from yeasts supports his views. Since many viruses grow in the cytoplasm

without killing the cell, they are disturbers *par excellence* of cytoplasmic metabolism and might be expected readily to cause the destruction, inactivation or malfunction of the grana. Viruses inhibiting the nucleus would be predicted to be not nearly so effective.

Ephrussi⁸ was the first to speculate concerning the chemical mechanism by which the respiratory grana of the yeast cell could be destroyed. He assumed that since acriflavine has an affinity for nucleic acids it was mutagenic and he found that it induced respiratory deficiency. Ephrussi was unaware of the fact that Stier and Castor⁹ had previously induced respiratory deficiency with cyanide, and Whelton and Phaff¹¹ had shown that ethylene oxide is extremely efficient in producing the same effect. It has become increasingly evident that a great variety of substances induce respiratory deficiency in yeasts: copper and manganous salts are recent additions. Whether these substances act directly as propanidine isethionate appears to, or indirectly as temperature¹² and caffeine adaptation, it seems clear that study of the phenomenon should be revealing in terms of the nature of the respiratory grana and therefore, of carcinogenesis.

THE NEW MARINE BIOLOGICAL STATION ON HELIGOLAND

By DR J. N. CARRUTHERS

National Institute of Oceanography, Wormley, Surrey

MANY years before the island of Heligoland passed from British to German ownership in 1890, it was popular with distinguished scientists from Germany and other Continental countries for marine biological pursuits, because the waters bordering the German mainland yield only a small part of the faunal range characteristic of the open sea.

In the Baltic, the low salinity of the German waters there is a limiting factor and in the North Sea the turbidity is such. Moreover, in the North Sea the wide belt of mainland shore which dries out at low tide militates against the establishment of a first-rate German marine biological station there. Well before 1850, men whose names were to become world-famous in the domain of marine biology were frequenting Heligoland because of the much better natural conditions which exist there.

So long ago as 1835, Ehrenberg had investigated the origin of bioluminescence while working on the island and, ten years later, Johannes Muller had

there formulated new ways of investigating the life of the open sea. In 1865 Anton Dohrn (later of Naples fame) and Ernst Haeckel of Jena were conducting researches from the island, and, within two years of its cession to Germany, a marine biological station had been founded with F. Heineke as first director. During the twenty-eight years of his tenure of the post, his famous work on the natural history of the herring and on the plaice was carried out. In those days the Station was housed in more than thirteen separate buildings and its own staff of eight scientists and sixteen technical assistants had to find room for sixteen guest workers. Not until it was possible (in 1920) to take possession of a large building freed from naval use did it become possible to conduct tuition courses, and the first of these was attended by a class of thirty.

Many British oceanographers will well remember Heineke's successor—the genial and talented W. Mielek, who was head of the Station during

Fig 1 General view from the water front

1920-33 When its enlargement was completed in 1937, the name "Wilhelm Meelok Haus" was given to part of the multi storied construction. The last director of the Station to be appointed before the Second World War was A. Hagmeier, who held the post on the island from 1934 until after hostilities had broken out. He remained the nominal director of the Station until his death in 1953. Until shortly before that time, he had been resident in Sylt at the dependant Ellenbogen Station near List. While there Hagmeier spent much effort in the furtherance of marine biological research and was able to adapt a vacated army building in List to provide a two roomed laboratory on the harbour side in which instructional courses could be given. Already by 1949 the number of visiting students had reached 170. When, in 1952, the island of Helgoland was made free of access again and declared ready for building operations to start Hagmeier was already prepared with plans for reconstituting the renowned Biologische Anstalt on it. Though it is not by any means the case that all German marine scientists were in favour of the project, the marine biologists for the most part were so.
